

## 5 Appendices

### 5.1 List of Abbreviations

#### Chemicals:

DTT	Dithiothreitol
NAD <sup>+</sup>	Nicotinamide adenine dinucleotide
PCMBS	p-chloromercuribenzenesulfonic acid
PEG	Polyethyleneglycol
PIP	di- $\mu$ -iodobis(ethylenediamine)diplatinum(II)nitrate
TCEP	tris-(2-carboxyethyl)phosphine

#### Datasets:

Nat-2	native protein
Malmn1	native protein with maltose, NAD <sup>+</sup> , Mn <sup>2+</sup>
Ag12	C25S/C174S double mutant with maltose, NAD <sup>+</sup> , Mn <sup>2+</sup>
Ag18	native protein with maltose, Co <sup>2+</sup>

#### Crystallographic terms:

Å	Angstrom, 0.1nm
BESSY II	Berliner Elektronenspeicherring - Gesellschaft für Synchrotronstrahlung m.b.H. II
B-factor	temperature factor
CAZY	Carbohydrate Active Enzyme Database
CSW	PDB abbreviation for cysteine-sulfinic acid

## Appendices

Cys-SOH	Cysteine-sulfenic acid
Cys-SO <sub>2</sub> H	Cysteine-sulfinic acid
DESY	Deutsches Elektronen Synchrotron
EMBL	European Molecular Biology Laboratory
GH4	Glycosyl Hydrolase family 4
MAD	Multiple wavelength Anomalous Dispersion
MIR	Multiple Isomorphous Replacement
MIRAS	Multiple Isomorphous Replacement with Anomalous Scattering
PDB	Protein Data Bank
rmsd	root mean square deviation

## 5.2 Theory of X-ray Crystallography

### 5.2.1 Diffraction of Waves: Bragg's Law

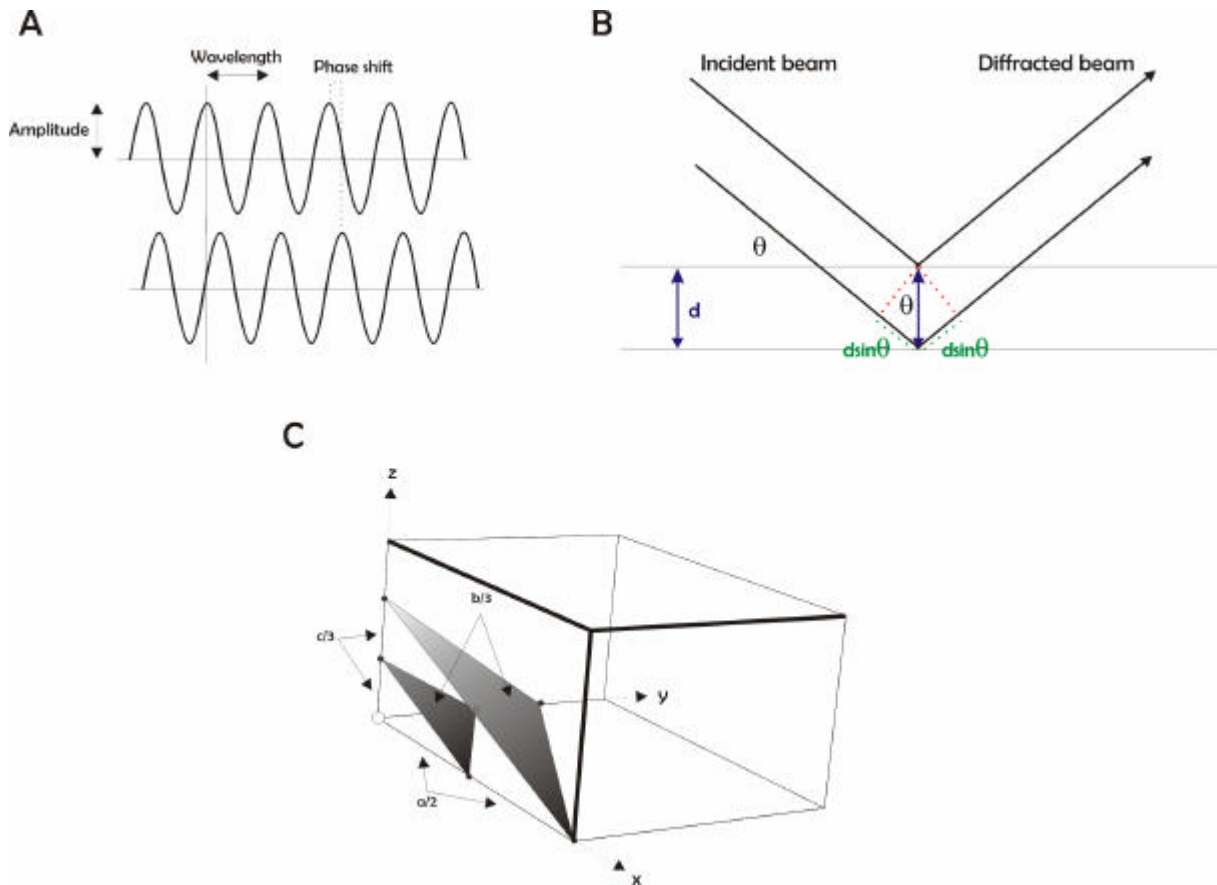

An X-ray is an electromagnetic wave with a wavelength of around 1 Å. As with all waves, it may be characterized by its wavelength, amplitude and phase (Figure 5.1, A). Diffraction of a wave occurs when the wave is scattered into directions other than that of the original beam without changing the wavelength. When an X-ray hits an electron, it sets the electron oscillating with the X-ray frequency, which may then radiate an X-ray photon of the same wavelength in a random direction as it returns to its unexcited state.

According to Bragg, the diffraction of X-rays by a crystal lattice can be described as reflection from a series of lattice planes. When an incoming wave (incident beam) hits a lattice plane under the angle  $\theta$ , it will be reflected (diffracted) to produce an outgoing wave (diffracted beam) that will have the same wavelength as the incident beam, however, the phase may differ. This diffraction is shown for beam A in Figure 5.1, B. The same diffraction will occur for all planes in the series, however the extra distance traveled, described by  $2d\sin\theta$ , will result in a phase shift of the diffracted beam. Positive interference will only occur if the extra distance the second beam travels ( $d$ ) is equal to an integer number of wavelengths ( $n\lambda$ ), as then the scattered beam is in phase with the first. This is described by Bragg's Law:

$$n\lambda = 2d\sin\theta$$

A set of parallel planes in a lattice is described by the indices h, k, l. These represent the fractional distance along each of the unit cell axes a, b, c which separate each plane in the series (Figure 5.1, C). Therefore each X-ray beam reflected from a set of planes can also be described by a set of indices h,k,l.

## Appendices

**Figure 5.1 Diffraction of waves from planes**

**A.** Wavelength and amplitude of a sinusoidal wave. Also shown is a second sinusoidal wave of the same wavelength and amplitude, but with a phase shift compared to the top wave. **B.** Bragg's Law. Shown are two planes of a crystal lattice with a distance of  $d$ . The difference between the distance traveled by the upper beam and the lower beam is shown as a green dotted line. **C.** Three-dimensional view of a unit cell, showing an example of the planes characterised by the  $h, k, l$  indices 2, 3, 3.

### 5.2.2 Reciprocal Space and the Ewald Sphere

In 1921, Ewald introduced a geometric construction which illustrates the relationship between the orientation of the crystal in the beam and the resulting X-ray reflections (Figure 5.2). A sphere is drawn around the crystal in position  $X$ . The X-ray beam enters this sphere in point  $I$ , and hits the crystal under the angle  $\theta$ . The reciprocal lattice is a lattice with the same symmetry elements as the real crystal lattice, but with unit cell dimensions  $a^*, b^*, c^*$ , which have the following relationship to the unit cell dimensions  $a, b, c$  of the real lattice:

$$a^* = \frac{1}{a}, \quad b^* = \frac{1}{b}, \quad c^* = \frac{1}{c}$$

## Appendices

At the point where the X-ray beam leaves the sphere, the origin (O) of a reciprocal lattice is placed. Based on this construction, for a given angle  $\theta$ , only those lattice points of the reciprocal lattice fulfill Bragg's law which fall onto the circumference of the sphere (here point P). These result in a reflection. For a complete diffraction data set the crystal has to be rotated in such a way that each lattice point of the reciprocal lattice passes through the Ewalds sphere at least once. For more details, see (Drenth, 1994; McRee, 1999).

Figure 5.2 Ewald sphere and the reciprocal lattice

### 5.2.3 The Phase Problem

The diffracted beam is scattered by the electrons in the protein. Therefore the diffraction data in principle contain the information on the location of the electrons in the unit cell. The electron density ( $\rho$ ) at a certain position in the unit cell ( $x, y, z$ ) is a function of the amplitude ( $|F|$ ) and the phase ( $\alpha$ ) of all diffracted beams:

$$\rho(xyz) = \frac{1}{V} \sum_{hkl} |F(hkl)| \exp[-2\pi i(hx + ky + lz) + i\alpha(hkl)]$$

## Appendices

The amplitudes or structure factors  $|F|$  are proportional to the intensities of the reflections and can thus be determined experimentally. However, the phase information is lost during the data collection. This is called the phase problem of crystallography.

### 5.2.4 Solving the Phase Problem by Isomorphous Replacement

The method of multiple isomorphous replacement (MIR) was first used by Max Perutz in 1953. It relies on the observation that a heavy atom, having a much higher concentration of electrons in a small volume, will scatter X-rays strongly. If a heavy atom can be introduced into a protein crystal via soaking or co-crystallisation, without otherwise changing the protein or the crystal lattice (i.e. the crystal remains isomorphous), the differences in the scattering intensities from this crystal to the native crystal can be exploited to indirectly determine the missing phase angles.

The structure factors from the native crystal ( $|F_P|$ ) and those of the heavy atom-derivatised crystal ( $|F_{PH}|$ ) are scaled together to remove any variation caused by crystal quality.  $|F_P|$  is then subtracted from  $|F_{PH}|$ , which gives the scattering intensities for only the heavy atoms ( $|F_H|$ ). This information is then used for the Patterson synthesis, a fourier synthesis in which the phases are assumed to be zero, the amplitudes are squared and a center of symmetry is added (Drenth, 1994). This will produce a map which gives the vectors between the heavy atoms in real space, however not their actual position. Using these vectors it is possible to determine the positions of the heavy atoms in the unit cell. With these sites, and the structure factors, the Fourier transformation can now be used to determine the unknown phases for these heavy atoms. From the heavy atom phases, the phases of the protein can be derived, and the initial electron density map of the protein can be calculated.

At this step there are still two possible solutions for every phase angle, only one of which is correct. This is the major limitation to structure determination via Single Isomorphous Replacement (SIR). The ambiguity can only be resolved by adding further information. In the Multiple Isomorphous Replacement (MIR) method, this is provided by further derivatives. Another method is to additionally use the anomalous signal produced by heavy atoms incorporated into the crystal (Single or Multiple Isomorphous Replacement with Anomalous Signal, SIRAS / MIRAS). Alternatively, data from a single crystal with one or more heavy atoms incorporated can be collected at several wavelengths (Multiple Wavelength Anomalous Dispersion, MAD). This has the advantage that non-isomorphism between different crystals is avoided.

### 5.2.5 Crystallographic Refinement

The nature of the data used to build the protein model, from data collection to phase solution to map calculation, is inherently full of error. To correct the model for this error, a crystallographic refinement is carried out.

In this, small shifts in the coordinates (bonds and angles) are introduced and the resulting energy values of the molecule are calculated. The aim is to identify the conformation with the lowest energy and the best fit to the experimental data (McRee, 1999). This is equivalent to finding the minimum of a target function  $E$  with:

$$E = E_{\text{chem}} + w_{\text{xray}} E_{\text{xray}}$$

where  $E_{\text{chem}}$  is the sum of the energy for all covalent and non-covalent interactions, including bond lengths and angles, torsion angles, non-bonded contacts, planar groups and chiral volumes.  $E_{\text{xray}}$  describes the differences between the observed structure factors,  $F_o$ , and those which can be calculated from the model,  $F_c$ :

$$E_{\text{xray}} = \sum_{hkl} \left[ |F_o(h)| - k |F_c(h)| \right]^2$$

where  $h$  is comprised of all the  $h,k,l$  indices of all reflections.  $w_{\text{xray}}$  is a weighting term which allows fine tuning of the influence of the X-ray term on the overall target function. A critical aspect of the refinement procedure is that the number of refined parameters (for each protein atom the position  $x$ ,  $y$ ,  $z$  and the B-factor) may not exceed the number of observations, that is the number of reflections collected from a crystal. The number of parameters can be reduced indirectly by restraining the stereochemistry to values derived from small molecule crystallography (Engh and Huber, 1991). The outcome of the refinement procedure therefore is an atomic model of the protein with optimised stereochemistry and a minimised overall energy which best fits the X-ray data collected.

The progress of the refinement is judged by the crystallographic R-factor,  $R_{\text{cryst}}$  which describes the deviation between the measured structure factors  $F_o$  and calculated  $F_c$ .

## Appendices

$$R_{cryst} = \frac{\sum_{hkl} |F_o(h) - k|F_c(h)|}{\sum_{hkl} |F_o(h)|}$$

As this factor is similar to the X-ray term, it may be artificially lowered when too many parameters are refined at the same time (over-fitting). A reference factor, termed  $R_{free}$ , was introduced by Brünger, where a subset of the reflections (usually 5-10% of the data collected) are excluded from refinement (test set) (Brünger, 1993). The  $R_{free}$  is then calculated as for  $R_{cryst}$ , but only against this test set.

## 5.3 Theory of SAXS

### 5.3.1 SAXS in an Ideal Solution

SAXS of biological macromolecules in solution follows the same rules that govern the scattering of X-rays by electrons in solid matter. As the distances involved in these proteins are much greater than interatomic distances, the scattering particles are described with a continuous electron density. In the following discussion the electron density at a single point,  $r$ , is represented by  $p(r)$  and the characteristic vector of the incident beam as  $s_0$ .

An ideal solution is one in which the particles within do not interact with each other and whose thermodynamic quantities follow a linear dependence on concentration. This is approximated in SAXS by the use of extremely dilute solutions and the measurement of a range of concentrations. The monodispersity of a solution describes the identity of the molecules within and holds true for particles with a defined shape such as native proteins. In several cases, such as denatured proteins, the molecules may be monodisperse in size, but show a large degree of polydispersity in shape. It is also possible to have polydispersity in size but monodispersity in shape with particles such as micelles, and polydispersity for both can be observed for aggregations. In an ideal monodisperse solution all particles scatter independently and the measured intensity is merely the sum of the intensities from each individual molecule:

$$I(s) = Ni_1(s)$$

$I(s)$  = experimental scattering intensity  
 $N$  = number of particles in sample  
 $i_1(s)$  = scattered intensity of the particle

It is possible to directly determine the size of the particle by knowing the intensity at the zero angle ( $s=0$ ) with the formula:

$$I(0)/c = \frac{N_A M}{\mu^2} (1 - \rho_0 \psi)^2$$

$I(0)$  = experimental scattering intensity at angle 0  
 $c$  = concentration  
 $N_A$  = Avagadro's constant  
 $M$  = molecular weight  
 $\mu = M/m$ , ratio of  $M$  to the number of electrons  
 $\rho_0$  = electron density distribution of particle at angle 0  
 $\psi$  = electronic partial specific volume of particle

## Appendices

Therefore the intensity at zero angle, scaled by the concentration, is proportional to the molecular weight and if  $\rho_0$ ,  $\psi$  and the intensity of the incident beam are known, the intensity at the origin will give the molecular weight.

### 5.3.2 Radius of Gyration

The movement of a particle within a solution follows Brownian motion. An ideal suspension of many particles would therefore assume all particles to be at all positions and in all orientations. This isotropic intensity distribution is proportional to the scattering for a single particle averaged over all orientations. Close to the origin (angle = 0), the scattering pattern of any single particle can be approximated by a Gaussian, the width of which is proportional to the square of the radius of gyration of the particle: the Guinier relation (Guinier and Fournet, 1955).

$$R_g^2 = \frac{\int_V \Delta\rho(\mathbf{r}) r^2 dV_r}{\int_V \Delta\rho(\mathbf{r}) r dV_r}$$

Here, the origin of the vector is taken to be the centre of mass of the particle, and the radius of gyration ( $R_g$ ) describes its sphericity. The relation of the radius of gyration to the scattering intensity close to the origin is described by:

$$I(s) \cong I(0) \exp\left(-\frac{4\pi^2}{3} R_g^2 s^2\right)$$

By graphing the natural log of  $I(s)$  against  $s^2$ , a linearised representation is created, as Guinier plot (Figure 5.3). From this plot, linear regression yields the radius of gyration from the slope, together with the intensity at the origin. However, a Guinier approximation does rely on an ideal monodisperse solution.

**Figure 5.3** Plots of the protein K-gliadin

**A.** Guinier ( $R_g$ ) plots for K-gliadin in 70% (v/v) aq. ethanol at concentrations of 9.3 (a), 4.7 (\*), 2.3 (E) and 1.3 (O) mg/ml. Limits for the Guinier approximation to be valid (QRg 61) are shown. **B.** Cross-section ( $R_c$ ) plots at concentrations of 9.3 (a), 4.7 (O), 2.3 (E) and 1.3 (\*) mg/ml. Limits for the cross-section approximation to be valid (QRc 61) are shown. Taken from (Thomson et al., 1999).

### 5.3.3 SAXS Data Processing

The scattering intensity from a single particle in an ideal solution cannot be measured directly, rather a set of intensities ( $I_{\text{exp}}(s_i)$  where  $I = 1 \dots N$ ) in a restricted angular range  $s_{\text{min}} < s < s_{\text{max}}$  is measured. This set will contain statistical errors and inaccuracies produced by the beam divergence, detector resolution etc, and so the task of data processing is restoring the  $I(s)$  from  $I_{\text{exp}}(s_i)$ . For an ideal solution,  $I(s)$  is related to the pair distribution function of the particle  $p(\mathbf{r})$  by the Fourier transform

$$I(s) = 4\pi \int_0^{D_{\text{max}}} \rho(\mathbf{r}) \frac{\sin 2\pi s r}{2\pi s r} dr$$

$D_{\text{max}}$  = maximum particle diameter

The function  $p(\mathbf{r})$  contains the same information as  $I(s)$  and the data processing can be done indirectly by restoring the  $p(\mathbf{r})$ . By providing the  $p(\mathbf{r})$ , the function  $I(s)$  is automatically extrapolated beyond the measured range of scattering vectors back to the origin. By using the entire scattering curve, the system is much less sensitive to small amounts of interactions or aggregations than the Guinier relation, and, like the latter, the effects of these interactions are restricted to the innermost part of the scattering pattern.

## Appendices

The program GNOM performs this indirect transform, identifying the multiplier which compensates between the quality of fit to the data and the smoothness of the  $p(\mathbf{r})$  function. The program visually compares solutions for different multiplier values automatically, finding the optimal solution or indicating that there may be problems in the assumptions (such as particle size,  $D_{\max}$ ) used.

### 5.3.4 Shape Determination

The analysis of a protein with known structure (ie. from crystallography or NMR results) is performed by the program CRY SOL (Svergun et al., 1995), which, as well as predicting the scattering curve produced by the protein, also takes into account the surrounding hydration shell and its effect on scattering.

The *ab initio* shape determination may take two approaches: the first is applied by the program SASHA and employs spherical harmonics to describe the particle shape, thereby making it possible to directly restore the shape from the scattering data. (Kozin et al., 1997). The second approach utilised by the programs DAMMIN and GASBOR, is based on a trial and error analysis of scattering patterns produced by models filled with spheres (dummy atoms) or, in the latter case, dummy residues. Examples of this approach are shown in Figure 5.4.

### 5.3.5 Instrumentation

The X-ray beam originating from a synchrotron source passes through a monochromator which produces a monochromatic beam. The vertical beam displacement reduces background radiation from the synchrotron, and reflection at a glancing angle from the toroidal mirror eliminates harmonics and focuses in the two directions normal to the beam. The pairs of slits eliminate parasitic scattering around the monochromatic beam, essential to reach the small angles required by SAXS. The camera contains another three pairs of slits, also to remove parasitic scattering, and defines the minimum observable scattering angle. The sample is fixed in a temperature controlled quartz capillary, but the sample-to-detector distance can be adjusted by moving the detector within the range of 0.5 and 10m.

## Appendices

**Figure 5.4** *Ab initio* Shape Determination with SAXS

**A.** Comparison of the atomic model of monomeric hexokinase (*red*) and the dummy residue (DR) models (*yellow*) of the monomeric (left) and dimeric (right) hexokinase. **B.** Atomic model of tetrameric yeast pyruvate decarboxylase superimposed with the DR model. **C.** Ab initio models of chitin binding protein: left, low resolution envelope produced by SASHA, middle and right, two most different DR models. The  $\alpha$ -chitin substrate is shown in *red*. From (Svergun et al., 2001).

## 5.5 CNS files for NAD<sup>+</sup>

Figure 5.6 Nomenclature of NAD<sup>+</sup>.

Atoms are labelled according to standard nomenclature. The apostrophe on the sugar ring atom labels are replaced by an asterisk in CNS and PDB files, according to CNS and PDB convention.

### 5.5.1 CNS Parameter File for NAD<sup>+</sup>

## 5.7 List of GH4 enzymes

<b>Abbreviation</b>	<b>Protein ID</b>	<b>Description</b>	<b>Organism</b>
AGLA_THEMA	O33830	$\alpha$ -glucosidase	<i>Thermotoga maritima</i>
AGAL_BACSU	O34645	$\alpha$ -galactosidase	<i>Bacillus subtilis</i>
MALH_FUSMR	O06901	Maltose-6'-phosphate glucosidase	<i>Fusobacterium mortiferum</i>
AGAL_ECOLI	P06720	$\alpha$ -galactosidase	<i>Escherichia coli</i>
CELF_BACSU	P46320	Probable 6-phospho- $\beta$ -glucosidase	<i>Bacillus subtilis</i>
CELF_ECOLI	P17411	6-phospho- $\beta$ -glucosidase	<i>Escherichia coli</i>
LPLD_BACSU	P39130	LPLD protein	<i>Bacillus subtilis</i>
GLVG_BACSU	P54716	Maltose-6'-phosphate glucosidase	<i>Bacillus subtilis</i>
ORF_1Bacillus	15613475	6-phospho- $\beta$ -glucosidase	<i>Bacillus halodurans</i>
ORF_2Bacillus	15612746	6-phospho- $\beta$ -glucosidase	<i>Bacillus halodurans</i>
ORF_Citrobacter	12249127	$\alpha$ -galactosidase	<i>Citrobacter freundii</i>
ORF_1Clostridium	15023397	Maltose-6'-phosphate glucosidase	<i>Clostridium acetobutylicum</i>
ORF_2Clostridium	15026514	6-phospho- $\alpha$ -glucosidase	<i>Clostridium acetobutylicum</i>
ORF_3Clostridium	18143856	Maltose-6'-phosphate glucosidase	<i>Clostridium perfringens</i>
ORF_Erwinia	13517313	Putative sugar hydrolase	<i>Erwinia rhapontici</i>
ORF_1Escherichia	12515750	Phospho- $\beta$ -glucosidase; cryptic	<i>Escherichia coli O157:H7 EDL933</i>
ORF_2Escherichia	12519092	$\alpha$ -galactosidase	<i>Escherichia coli O157:H7 EDL933</i>
ORF_3Escherichia	12518523	Putative 6-phospho- $\beta$ -glucosidase	<i>Escherichia coli O157:H7 EDL933</i>
ORF_Klebsiella	12667493	6-phospho- $\alpha$ -glucosidase	<i>Klebsiella pneumoniae</i>
ORF_1Listeria	16799601	Similar to 6-phospho- $\beta$ -glucosidase	<i>Listeria innocua</i>
ORF_2Listeria	16799615	Similar to 6-phospho- $\beta$ -glucosidase	<i>Listeria innocua</i>
ORF_3Listeria	16801516	Similar to 6-phospho- $\beta$ -glucosidase	<i>Listeria innocua</i>
ORF_4Listeria	16802564	Similar to 6-phospho- $\beta$ -glucosidase	<i>Listeria monocytogenes EGD-e</i>
ORF_5Listeria	16802579	Similar to 6-phospho- $\beta$ -glucosidase	<i>Listeria monocytogenes EGD-e</i>
ORF_1Mesorhizobium	14026141	$\alpha$ -galactosidase	<i>Mesorhizobium loti</i>
ORF_2Mesorhizobium	14026146	$\alpha$ -galactosidase	<i>Mesorhizobium loti</i>
ORF_1Salmonella	16502875	Phospho- $\beta$ -glucosidase B	<i>Salmonella enterica</i>
ORF_2Salmonella	16505287	$\alpha$ -galactosidase	<i>Salmonella enterica</i>
ORF_3Salmonella	16419834	Phospho- $\beta$ -glucosidase	<i>Salmonella typhimurium LT2</i>
ORF_1Sinorhizobium	15141450	Probable $\alpha$ -galactosidase	<i>Sinorhizobium meliloti</i>
ORF_2Sinorhizobium	15141176	Probable 6-phospho- $\beta$ -glucosidase	<i>Sinorhizobium meliloti</i>
ORF_1Streptomyces	6855385	Putative sugar hydrolase	<i>Streptomyces coelicolor A3(2)</i>
ORF_2Streptomyces	6900960	Putative sugar hydrolase (partial)	<i>Streptomyces coelicolor A3(2)</i>
ORF_3Streptomyces	6137043	Putative $\alpha$ -galactosidase	<i>Streptomyces coelicolor A3(2)</i>
ORF_patent	10059896	Sequence 8 from patent US 5985622	<i>Erwinia rhapontici</i>
ORF_Vibrio	9655770	6-phospho- $\beta$ -glucosidase	<i>Vibrio cholerae</i>
ORF_Yersinia	15978271	Putative glycosyl hydrolase	<i>Yersinia pestis</i>

## Appendices

### 5.8 Curriculum vitae

Full Name: Jacinta Anne Lodge

Date of Birth: 11.08.1975

Nationality: Australian

#### Education:

<b>Primary School</b>	1980-1982 1983 1984-1987	Lutheran Primary School, Hamilton Roslyn Primary School, Geelong Grovedale Primary School, Geelong
<b>High School</b>	1988-1993	Belmont High School, Geelong, Australia Achieved Victorian Certificate of Education Subjects Biology, Chemistry, Physics, Maths, Music - Solo Performance, English Score: 132/164
<b>University</b>	1994-1997	La Trobe University, Melbourne, Australia Bachelor of Science (Biological) with Honours Honours (Masters equivalent) Score: H1 (first class)

#### Career-related Employment:

01.12.96 - 31.01.97	<b>LaTrobe University</b> Department of Biochemistry Summer Studentship Trypsin inhibition by Anthracyclins
01.02.97 – 30-10.97	<b>La Trobe University</b> Department of Biochemistry Honours Student (Masters equivalent) Identification and purification of proteases from <i>Nicotiana tabacum</i>
01.05.97 - 31.02.98	<b>LaTrobe University</b> Department of Biochemistry Laboratory Technician Care of plant glasshouse and caterpillar colony. Dissection of caterpillars
01.03.98 - 31.03.99	<b>Hexima, Ltd</b> Research Assistant Agrobacterium mediated transformation of cotton plants for insect resistance. Development of ELISA-based screening technique for transformants. Production and purification of rabbit antibodies.

## Appendices

- 20.09.99 - 30.07.00      **Max-Planck Forschungsstelle "Enzymologie der Proteinfaltung"**  
Halle/Saale  
Studentship  
Mitochondrial import. *In vitro* protein production, radioactive assays
- 01.08.00 - current      **Freie Universität Berlin**  
Institut für Chemie - Kristallographie  
PhD Student  
Protein Crystallography: Cloning, expression and purification of proteins for crystal production. Protein crystallisation. X-ray data collection and processing using rotating anode on X-ray generators and synchrotronsources. Building and refinement of protein structures.

### Seminars and Conference Participation

- 1997 Australian Society for Biochemistry and Molecular Biology, Melbourne, Australia  
1998 Lorne Protein Conference, Lorne, Australia  
1999 MPI-Halle, IMB-Jena combined meeting, Wittenberg, Germany  
2001 German Biochemical Society Meeting, Bochum, Germany  
    Poster presentation  
2002 Heart of Europe Crystallography Meeting, Goslar, Germany  
    Talk: A new glucosidase fold  
2003 DGK Meeting, Berlin, Germany  
    Poster presentation

### 5.9 Publication of this work

#### Talk:

“A new glucosidase fold”

2002 Heart of Europe Crystallography Meeting, Goslar, Germany. September 25 – 27, 2002.

#### Poster Presentations:

Lodge, J.A., Maier, T., Raasch, C., Leibl, W. and Strater, N.

“The crystal structure of *Thermotoga maritima*  $\alpha$ -glucosidase A defines a new clan of NAD<sup>+</sup>-dependent glucosidases”. Elfte Jahrestagung der Deutschen Gesellschaft für Kristallographie, Berlin, Germany. March 10 – 12, 2003

Lodge, J.A., Maier, T., Raasch, C., Leibl, W. and Strater, N.

“A new clan of glucosidases: The crystal structure of *Thermotoga maritima*  $\alpha$ -glucosidase A”. Seventh International School on the Crystallography of Biological Macromolecules, Como, Italy. May 10 - 14, 2003.

#### Publication:

Lodge, J.A, Maier, T., Raasch, C., Leibl, W. and Strater, N. (2003)

"Crystal structure of family 4 *Thermotoga maritima* AglA defines a new clan of NAD<sup>+</sup>-dependent glucosidases". *J. Biol. Chem.* **278** (21):19151-19158.

#### PDB Submission:

The atomic coordinates and structure factors (code 10BB) have been deposited in the Protein Data Bank, Research Collaboratory for Structural Bioinformatics, Rutgers University, New Brunswick, NJ. (<http://www.rcsb.org/>).
