2 Abstrakt

Infektionen mit extended-spectrum Betalaktamase-produzierenden *Enterobacteriaceae* (ESBL-E) sind assoziiert mit einer erhöhten Mortalität. Die Unterschiede im klinischen Bild, die den verschiedenen Spezies der ESBL-E oder ESBL-Genotypen geschuldet sind, wurden noch nicht ausreichend untersucht. Wir führten eine Kohortenstudie zur Bewertung der Risikofaktoren für Sterblichkeit in Fällen mit einer ESBL-E-Bakterämie (*K. pneumoniae* oder *E. coli*) und zur Bewertung der Risikofaktoren für Sepsis mit Organversagen durch. Eingeschlossen wurden alle Patienten unserer Institution mit einer ESBL-E-Bakterämie in der Zeit von 2008 bis 2011. Epidemiologische Basisdaten, zugrundeliegende Komorbiditäten, Ursprung der Bakterämie, Schweregrad der Sepsis und Daten zur zeitlichen Verzögerung bis zu Beginn der adäquaten antibiotischen Therapie wurden gesammelt. Die Isolate wurden mittels PCR auf das Vorhandensein von ESBL-Genen und plasmidvermittelten AmpC β -Laktamasen untersucht. Wir führten eine Cox Regressionsanalyse zur Mortalität und eine multivariable logische Regression zu den Risikofaktoren für eine Sepsis mit Organversagen durch. Insgesamt wurden 219 Fälle in die Analyse eingeschlossen: 71,3% mit *E. coli*, 26,9% mit *K. pneumoniae*. Wir fanden keine signifikanten Unterschiede bei der Krankenhaussterblichkeit (ESBL-*E. coli* 23.8% vs. ESBL-*K. pneumoniae* 27.1%, $p=0.724$). Bakterämien mit *K. pneumoniae* (OR 4.5, $p<0.001$), Lebererkrankungen (OR 3.4, $p=0.004$) oder Nierenerkrankungen (OR 6.8, $p<0.001$) waren mit einem erhöhten Risiko einer Sepsis mit Organversagen vergesellschaftet. Wir fanden signifikante Unterschiede im klinischen Bild zwischen ESBL-E Bakterämien mit *K. pneumoniae* und Bakterämien mit *E. coli*. Bakterämien mit *K. pneumoniae* bieten ein weitaus schwerwiegenderes klinisches Bild und sind mit anderen Risikofaktoren vergesellschaftet als Bakterämien mit *E. coli*. Behandlungs- und Präventionsstrategien sollten dementsprechend angepasst werden.

3 Abstract

Infections with extended-spectrum beta-lactamase-producing *Enterobacteriaceae* (ESBL-E) are associated with increased mortality. Outcome differences due to various species of ESBL-E or ESBL genotypes are not well investigated. We conducted a cohort study to assess risk factors for mortality in cases of ESBL-E bacteremia (*K. pneumoniae* or *E. coli*) and the risk factors for sepsis with organ failure. All consecutive patients of our institution from 2008 to 2011 with bacteremia due to ESBL-E were included. Basic epidemiological data, underlying comorbidities, origin of bacteremia, severity of sepsis and delay of appropriate anti-infective treatment were collected. Isolates were PCR-screened for the presence of ESBL genes and plasmid-mediated AmpC β-lactamases. Cox proportional hazard regression on mortality and multivariable logistic regression on risk factors for sepsis with organ failure was conducted. 219 cases were included in the analysis: 73.1% due to *E. coli*, 26.9% due to *K. pneumoniae*. There was no significant difference in hospital mortality (ESBL-*E. coli*, 23.8% vs. ESBL-*K. pneumoniae* 27.1%, p=0.724). However, the risk of sepsis with organ failure was associated in cases of *K. pneumoniae* bacteremia (OR 4.5, p<0.001) and patients with liver disease (OR 3.4, p=0.004) or renal disease (OR 6.8, p<0.001). We found significant differences in clinical presentation of ESBL-E bacteremia due to *K. pneumoniae* compared to *E. coli*. As *K. pneumoniae* cases showed a more serious clinical presentation as *E. coli* cases and were associated with different risk factors, treatment and prevention strategies should be adjusted accordingly.

4 Eidesstattliche Versicherung

„Ich, Christian Johannes Christos Sakellariou, versichere an Eides statt durch meine eigenhändige Unterschrift, dass ich die vorgelegte Dissertation mit dem Thema: „Sepsis durch Breitspektrum β -Laktamaser (ESBL) bildende *K. pneumoniae* und *E. coli*: Vergleichende Analyse der Krankheitsschwere, des Zeitpunkts der Antibiotikatherapie und des ESBL Genotyps“

selbstständig und ohne nicht offengelegte Hilfe Dritter verfasst und keine anderen als die angegebenen Quellen und Hilfsmittel genutzt habe.

4.1 Ausführliche Anteilserklärung an der erfolgten Publikation

Publikation: Autoren: Christian Sakellariou, Stephan Gürntke, Christian Kohler, Ivo Steinmetz, Yvonne Pfeifer, Petra Gastmeier, Frank Schwab, Axel Kola, Maria Deja, Rasmus Leistner, Titel: Sepsis caused by extended-spectrum beta-lactamase (ESBL)-positive *K. pneumoniae* and *E. coli*: Comparison of severity of sepsis, delay of anti-infective therapy and ESBL genotype, Zeitschrift: PLOS ONE, Erscheinungsjahr: 2016

Beitrag im Einzelnen:

Diese Publikation wurde in geteilter Erstautorenschaft mit Herrn Stephan Gürntke veröffentlicht.

Konzeption und Gestaltung:

- Mitentwicklung der Forschungsfrage
- Entwicklung eines Fragebogens zur standardisierten Erfassung der krankheitsbezogenen Daten bei Patienten mit einer Sepsis durch *E. coli* und *K. pneumoniae*
- Mitarbeit bei der Entwicklung des Studienkonzepts
- Ausführliche Literaturrecherche, logistische Planung

Durchführung:

- Standardisierte Erhebung, Validierung und Plausibilitätsprüfung der Daten von Patienten mit einer *E. coli*-Infektion, Zusammenführung mit den Daten der Patienten mit *K. pneumoniae*-Infektion
- Erneute Validierung und Plausibilitätsprüfung des Gesamtdatensatzes durch stichprobenartige Überprüfung
- Pflege der Datenbanken
- Sammlung und teilweise Verarbeitung der Isolate und Versand an kooperierende Einrichtung (RKI Wernigerode)

Analyse:

- Vorbereitung und Bereinigung der Daten in Microsoft Excel zur Analyse mit SPSS
- 22
- Erarbeitung der Tabellen und Grafiken.

Publikation:

- Selbständige Erstellung des Manuskripts unter Rücksprache mit den Koautoren
- Zuarbeit bei den Korrekturen nach Review des Artikels.

6.1 Abstract

Infections with extended-spectrum beta-lactamase-producing *Enterobacteriaceae* (ESBL-E) are associated with increased mortality. Outcome differences due to various species of ESBL-E or ESBL genotypes are not well investigated. We conducted a cohort study to assess risk factors for mortality in cases of ESBL-E bacteremia (*K. pneumoniae* or *E. coli*) and the risk factors for sepsis with organ failure. All consecutive patients of our institution from 2008 to 2011 with bacteremia due to ESBL-E were included. Basic epidemiological data, underlying comorbidities, origin of bacteremia, severity of sepsis and delay of appropriate anti-infective treatment were collected. Isolates were PCR-screened for the presence of ESBL genes and plasmid-mediated AmpC β-lactamases. Cox proportional hazard regression on mortality and multivariable logistic regression on risk factors for sepsis with organ failure was conducted. 219 cases were included in the analysis: 73.1% due to *E. coli*, 26.9% due to *K. pneumoniae*. There was no significant difference in hospital mortality (ESBL-*E. coli*, 23.8% vs. ESBL-*K. pneumoniae* 27.1%, p=0.724). However, the risk of sepsis with organ failure was associated in cases of *K. pneumoniae* bacteremia (OR 4.5, p<0.001) and patients with liver disease (OR 3.4, p=0.004) or renal disease (OR 6.8, p<0.001). We found significant differences in clinical presentation of ESBL-E bacteremia due to *K. pneumoniae* compared to *E. coli*. As *K. pneumoniae* cases showed a more serious clinical presentation as *E. coli* cases and were associated with different risk factors, treatment and prevention strategies should be adjusted accordingly.

6.2 Introduction

Infections due to extended-spectrum beta-lactamase-producing *Enterobacteriaceae* (ESBL-E) are associated with impaired outcome compared to infections with susceptible pathogens [1-3]. Former studies on ESBL-E bacteremia proved that a delay of adequate antimicrobial chemotherapy can be an important factor on mortality [1, 2, 4]. This effect seems to be the most evident in cases of septic shock or organ failure [5]. This is even more important since there is evidence that infections due to *K. pneumoniae* are associated with a worse course compared to other *Enterobacteriaceae* [4, 6, 7]. However, studies concerning ESBL-E infections often do not differentiate between the infecting species. There are only few studies comparing outcome parameter of different *Enterobacteriaceae* [4, 6, 8-10]. To analyze the effect of the different ESBL-E species on mortality and on the clinical presentation, we conducted a cohort study comparing cases of ESBL-positive *K. pneumoniae*- and *E. coli* bacteremia including data on the timing of their antimicrobial treatment.

6.3 Methods

6.3.1 Study design

We conducted a retrospective cohort study on patients with bacteremia due to ESBL-E. The setting of this study was the Charité University Hospital in Berlin, Germany, a tertiary care university hospital with over 120,000 admissions per year. Previously, our ethics committee approved the study without informed consent. The patient data based on secondary clinical information. The biological material was obtained clinically and analyzed by a separate institution after anonymization in our institution (reference number EA4/031/11). Parts of the study have been published in different analyses including differing data sets [10, 11].

All inpatients with ESBL-E bacteremia (*E. coli* or *K. pneumoniae*) diagnosed between January 1st, 2008 and December 31st 2011 were included. The bacteremia was classified as hospital onset if a positive blood culture was collected after the third hospital day. In case of more than one cultured organism in the first positive blood culture, the episode was defined as polymicrobial bacteremia. If the patient showed multiple subsequent positive blood cultures, the first positive blood culture lead to the allocation to one of the two pathogens and this episode was included in the analysis. Underlying comorbidities were assessed according to the method by Charlson et al. [12]. The comorbidities were collected using the patients' ICD-10 codes and grouped for the calculation of the Charlson comorbidity index (CCI) according to the method by Thygesen et al. [13].

Further clinical parameters were collected by analysis of the patients' files. To assess the origin of ESBL bacteremia we collected data on earlier infections during the analyzed hospital stay. These infections were due to same ESBL-positive organisms as the corresponding bacteremia episode and at maximum 14 days prior to the bacteremia onset. The infections were assessed according to the CDC definitions [14]. Primary bacteremia was defined as central venous catheter (CVC) <48h prior to the bacteremia onset without presence of another ESBL-E infection. Mortality was defined as in-hospital mortality and ESBL colonization was assessed as colonization with ESBL-E prior to the

bacteremia episode at any site. Sepsis, severe sepsis, and septic shock were defined according to the definitions of the consensus conference of the American College of Chest Physicians and the Society of Critical Care Medicine which also find application in Germany [15, 16]. Delay of anti-infective treatment (DAT) was defined as initiation of effective treatment ≥ 1 day after onset of bacteremia. Effective treatment was defined as an antimicrobial agent the ESBL-positive organism was tested susceptible against.

6.3.2 Microbiological methods

Species identification and antimicrobial susceptibility testing was performed using the Vitek 2 automated system with interpretation and antibiogram reporting according to the CLSI standard [17]. Confirmation of ESBL production was performed by a minimum inhibitory concentration dilution test on a multiwell microtiter plate. Three cephalosporins (cefotaxime, ceftazidime, cefpodoxime) were tested alone and in combination with ESBL inhibitor clavulanic acid. All verification swabs were inoculated onto chrome ID ESBL agar (BioMerieux). ESBL-positive isolates were affirmed by Double Disc Synergie Testing using 3rd generation cephalosporins with/without clavulanic acid (Mast). Species confirmation was done by API20E (BioMerieux). The isolates were screened for the presence of different ESBL genes (blaTEM-type, blaSHV-type, blaCTX-M-1/2/9 group) by polymerase chain reaction (PCR) and subsequent sequencing [18]. If none of these ESBL genes could be identified, additional PCR tests for the presence of plasmid-mediated AmpC β -lactamases [19] and further ESBL genes (blaCTX-M-8-type, blaCTX-M-26-type) were performed [20]. Furthermore, basic bacterial typing of all ESBL-positive *E. coli* isolates was performed by a PCR-based method for determination of the four major *E. coli* phylogenetic groups [21].

6.3.3 Statistical methods

Parameters in the univariate analysis were tested using the Wilcoxon rank sum test for continuous variables and the Fisher's exact test for categorical variables. For the analysis of factors associated to severity of illness, the categories were transformed to a binary category as bacteremia (bacteremia and sepsis) vs. sepsis with organ failure (severe sepsis and septic shock). Clinical parameter of *E. coli*- and *K. pneumoniae*- cases were compared using univariate analysis. Multivariable binary logistic analysis using a stepwise forward regression was computed for the analysis of clinical risk factors for sepsis with organ failure. We compared the clinical parameter of the deceased patients and the alive discharged patients using univariate analysis. We calculated adjusted hazard ratios for in-hospital death using Cox-proportional hazard regression using a stepwise forward approach. In both multivariable analyses, parameters with p-values <0.20 in the univariate analyses were considered in the analysis. Variables with p-values <0.05 were included and variables with $p \geq 0.05$ were excluded. All tests of were two tailed with a p-value <0.05 considered to be significant. Data was analyzed using IBM SPSS Statistics Version 22.

6.4 Results

We identified altogether 243 consecutive cases of bacteremia, 177 cases due to ESBL-positive *E. coli* (73.1%) and 66 cases due to *K. pneumoniae* (27.2%) together. No case showed both analyzed pathogens in the same blood culture. From twenty-three cases (9.9%), sufficient data was not available and therefore excluded. The remaining 219 cases were analyzed (n=160, 73.1% due to *E. coli* and n=59, 26.9% due to *K. pneumoniae*). We found an increasing risk for mortality in relation to the applied definitions for severity of sepsis (Fig 1). The characteristics of the analyzed cohort stratified by infecting organism are given in S1 Table. Patients suffering from ESBL-positive *K. pneumoniae* bacteremia (ESBL-KP-Bac) were younger than the compared patients with ESBL-positive *E. coli* bacteremia (ESBL-EC-Bac). They more often had a secondary bacteremia due to a surgical site infection and more often an unknown source of infection. ESBL-KP-Bac was more often associated with sepsis with organ failure. Patients with sepsis with organ failure showed significantly reduced DAT compared to patients presenting with bacteremia only (Median 0 days, IQR 0;2 days vs. Median 2 days, IQR 0;3 days, p=0.003). Patients with ESBL-KP-Bac showed an increased mortality compared to ESBL-EC-Bac (27.1% vs. 23.8%) but not statistical significant. ESBL-EC-Bac however, was more common among patients with previous urinary tract infection. The mostly used antimicrobial agents after infection onset were carbapenems: 71.2% (n=156), quinolones 12.3% (n=27), tigecycline 5.0% (n=11), piperacillin-tazobactam 2.3% (n=5) and gentamicin 2.3% (n=5).

6.4.1 Microbiology parameter

In the clinically reported antibiogram, 98.6% (n=216) isolates were resistant to piperacillin/ tazobactam, 98.2% (n=215) to ceftazidime, 69.4% (n=152) to ciprofloxacin and 43.4% (n=95) to gentamicin. None of the included isolates was reported resistant to the carbapenems imipenem or meropenem. Of the 219 isolates, 88.5% (n=194) were available for further ESBL genotype analysis; the remaining 25 were not retrievable. The distribution of the ESBL genotypes is shown in Tables 1 and 2 with overall CTX-M-15, CTX-M-1, CTX-M-14 and SHV-5 as most common types. One-hundred and seven isolates (55.2%) carried two or more TEM- or SHV-type beta-lactamases. Seven isolates (3.6%) did not carry an ESBL gene. Five showed either TEM-181, TEM-1 or SHV-1 overproduction, one was CMY-positive and one did not show any beta-lactamase at all. The distribution pattern of the phylogenetic groups within the analyzed 140 *E. coli* isolates was B2 (33.6%, n=47), A (28.6%, n=40), D (26.4%, n=37) and B1 (11.4%, n=16).

Table 1. Univariate analysis of clinical parameter in patients presenting with sepsis with organ failure and bacteraemia.

Parameter	Bacteremia (n=138)	Sepsis with organ failure (n=81)	P-value

Continuous parameter are displayed as median (interquartile range), categorical parameter as number (percentage). ESBL, extended-spectrum beta-lactamase. *, parameter was included in the Cox regression analysis on risk factors for death.

6.4.2 Factors associated with sepsis with organ failure

Table 3 shows the results of the multivariable analysis on risk factors for sepsis with organ failure. The *K. pneumoniae* cases were associated with 4.5 times higher odds for an organ failure at presentation. Furthermore, sepsis with organ failure was associated with liver disease (OR 3.3) and moderate to severe renal disease (OR 6.835).

Table 3. Results of the multivariable binary logistic regression analysis on risk factors for sepsis with organ failure

Parameter	P-value	OR	Upper – Lower CI 95
Moderate to severe renal disease	<0.001	6.835	3,485-13,405
Liver disease	0.004	3.347	1,463-7,658
Bacteremia due to <i>E.coli</i>	<0.001	1=reference	
Bacteremia due to <i>K. pneumoniae</i>		4.499	2,168-9,337

OR, odds ratio. CI 95, 95% confidence interval.

6.4.3 Factors associated with in-hospital mortality (Cox-proportional hazard analysis)

The results of the univariate analysis on in-hospital mortality are displayed in *Table 2*. In order to assess the effect of the infecting organism (*E. coli* vs. *K. pneumoniae*) on mortality this parameter was also considered in the Cox-proportional hazard regression. The deceased had significantly higher CCIs. These patients also had significantly more often a hospital onset bacteremia, sepsis with organ failure, prior episodes of lower respiratory tract infection, intra-abdominal infection or primary bacteremia, underlying heart disease, liver- or renal disease. The survivors had more commonly a urinary tract infection prior to their bacteremia. The results of the Cox-proportional hazard regression (*Table 4*) showed that sepsis with organ failure was associated with a 4.5-fold higher hazard for mortality, renal disease and liver disease with 2.7-fold and 1.8-fold elevated hazard. The only protective factor was urinary tract infection that was associated with a hazard reduction for mortality of about 61% (HR 0.39). There was no statistically significant difference in the mortality risk between both species. *Fig 2* shows the Kaplan Meier plot for cumulative survival stratified by ESBL-E species in relation to length of stay after onset of sepsis.

Table 4. Results of the Cox-proportional hazard regression on clinical risk factors for death after ESBL-E sepsis.

Parameter	P-value	HR	Upper – Lower CI 95
Bacteremia due to <i>E.coli</i>	0.060	1=reference	
Bacteremia due to <i>K. pneumoniae</i>		1.801	0.975 – 3.330
Urinary tract infection	0.007	0.360	0.172 – 0.754
Bacteremia/sepsis	<0.001	1=reference	
Severe sepsis/ septic shock		4.543	2.134 – 9.673
Liver disease	0.045	1.801	1.013 – 3.203
Moderate/ severe renal disease	0.016	2.675	1.198 – 5.973

HR, hazard ratio. CI 95, 95% confidence interval.

6.5 Discussion

In this study ESBL-KP-Bac bacteremia was associated with different origin, with sepsis with organ failure and younger age compared to ESBL-EC-Bac cases (S1 Table). Our results underline the findings of previous studies showing that *K. pneumoniae* infections are associated with more serious illness than *E. coli* infections [4, 6, 7, 22]. Even though *K. pneumoniae* bacteremia was not associated with delayed adequate anti-infective treatment it was associated with slightly increased mortality, but it did not reach the significance level. The small sub-cohort of ESBL-KP-Bac might explain this.

Several studies show that a delay of adequate antimicrobial chemotherapy is a risk factor for in-hospital death [1, 2, 4]. In our cohort, the association of sepsis with organ failure and reduced DAT demonstrate most likely the realization of the German sepsis guidelines [23]. Patients who present with severe sepsis or septic shock are recommended to be immediately initiated with an early initial broad-spectrum treatment including reserve antibiotics e.g. carbapenems. In our study, the presentation of severe sepsis happened before the initiation of the antimicrobial therapy. Hence, the observed association between disease severity and reduced DAT represents the response to the severity of the disease and not the cause of the disease. This refers to the observation that in sepsis with organ failure, an early effective antimicrobial therapy is associated with significantly reduced mortality risk [24]. Even though most cases of sepsis with organ failure received appropriate antimicrobial therapy within the first day, more than 25% showed a DAT of more than 1 day. This observation might at least partly explain the remaining high mortality (51.9%) in patients with severe sepsis and septic shock.

ESBL-KP-Bac cases were associated with sepsis with organ failure. However, they did not show significant differences in comorbidities compared to ESBL-EC-Bac cases (S1 Table). This might be explained by a potentially higher virulence of *K. pneumoniae* compared to *E. coli*. An earlier study on length of hospital stay included parts of the data at hand. Altogether 1.851 cases of bacteremia with (ESBL-positive and –negative) *Enterobacteriaceae* were analyzed then [10]. In that study, *K. pneumoniae* cases were associated with significantly prolonged hospital stay compared to *E. coli* cases. This most likely indicates a more problematic course of infection in *K. pneumoniae* cases. However, in that former study no data on antimicrobial therapy was analyzed [10]. Our present

results support the previous findings after adjustment for timely and adequate antimicrobial therapy.

The primary source of bacteremia differed significantly between both pathogens. While *E. coli* bacteremia was mostly found secondary to a urinary tract infection, *K. pneumoniae* cases were associated with surgical site infection (SSI), lower respiratory tract infection (LRTI) and unknown origin. Besides undetected colonization, the latter could be explained by health-care associated transmission. However, all sites of origin (SSI, LRTI and transmission) are likely since *K. pneumoniae* is often identified as outbreak pathogen [25, 26] and shows higher transmission potential than *E. coli* [27].

Urinary tract infection (UTI) as possible source of bacteremia was found less often associated with the development of a fatal bacteremia. This goes along with former studies on ESBL-E bacteremia [7, 28]. ESBL-E are common pathogens of urinary tract infections. A prior microbiologically diagnosed ESBL-E UTI might have supported an early initiation of anti-infective treatment at presentation of a secondary bacteremia.

Even though there are significant differences in the ESBL genotype distribution of both pathogens, none of these genotypes was associated with increased mortality. However, our data confirms that the most common genotypes among clinical ESBL-positive *E. coli* isolates in the United States and in Europe are currently CTX-M-15 and CTX-M-14 [29, 30]. In our *K. pneumoniae* isolates the most common ESBL genotypes were CTX-M-15 and SHV-5 which is also commonly observed in Europe [3, 31].

In our study, most of the isolates were reported resistant against piperacillin-tazobactam (pip-taz) due to their ESBL positivity. In 2011, CLSI recommended the interpretation of the breakpoint should be reported as found, irrespective of whether there was ESBL production [32]. Based on the current CLSI breakpoints, 35.2% of our isolates would be resistant to pip-taz. However, in this study, we focused on the results of the treatment based on the reported antibiogram. This goes along with the observed antimicrobial treatment showing carbapenems as mostly used agent, followed by quinolones.

This study has limitations. It was performed retrospectively and only ESBL-positive infections were assessed. Potential differences to ESBL-negative infections cannot be determined. The study was conducted at a single center. However, the data were collected from all patients within our hospital, regardless the respective department and likely represents the current course of these kind of infections in comparable hospitals.

The species identification was performed using the Vitek 2 system. Since Vitek 2 cannot differentiate *K. pneumoniae* and *K. variicola*, it is possible that up to 10% of our analyzed *K. pneumoniae* isolates are *K. variicola*. Future studies on carbapenem resistance should include ertapenem. Some isolates produce weak carbapenemases and may show decreased susceptibility to this substance only.

In conclusion, ESBL-positive *K. pneumoniae* bacteremia compared to ESBL-positive *E. coli* bacteremia is often associated with complicated infection and less often with uncomplicated infection such as urinary tract infection. In this small study group, pathogen on species level and genotypes were not associated with mortality, but with well-known factors as sepsis with organ failure. Knowledge of colonization and source of infection should be considered for empiric anti-infective treatment, especially in patients with septic shock to reduce DAT and mortality. Infections with ESBL-positive *K. pneumoniae* should be considered as more serious infections than comparable *E. coli* infections. Treatment and prevention strategies should be adjusted accordingly.

6.6 Acknowledgement

CS and SG contributed equally to this article. We thank Sybille Müller-Bertling and Christoph Eller for excellent technical assistance. We furthermore thank Ivo Steinmetz for his laboratory support. This project was executed within the scope of the RESET research consortium and was funded partly by grants from the Federal Ministry of Education and Health, Germany (01KI1013H to RL and PG).

6.8 Supporting Information

S1 Table. Univariate analysis of clinical parameter in patients with ESBL-positive bacteremia due to *E. coli* in comparison to *K. pneumoniae*.

Univariate analysis			
Parameter	<i>E. coli</i> (n=160)	<i>K. pneumoniae</i> (n=59)	P-value
Age years / Age < 61 years	72 (45.0%)	37 (62.7%)	0.023
Male sex	105 (65.6%)	41 (69.5%)	0.631
Charlson comorbidity index (CCI)	5 (3; 9)	6 (4; 8)	0.197
In-hospital death	38 (23.8%)	16 (27.1%)	0.724
Polymicrobial bacteraemia	22 (13.8%)	7 (11.9%)	0.825
Days from admission to onset	6 (1; 21)	19 (2; 52)	0.005
Days from onset to discharge/death	14 (8; 40)	12 (7; 25)	0.300
Hospital onset	92 (57.5%)	41 (69.5%)	0.120
ESBL colonization before onset	106 (66.3%)	32 (54.2%)	0.116
Origin of ESBL-E bacteraemia			
Urinary tract infection	63 (39.4%)	12 (20.0%)	0.010
Lower respiratory tract infection	25 (15.6%)	15 (25.4%)	0.115
Intra-abdominal infection	17 (10.6%)	5 (8.5%)	0.802
Surgical site infection	3 (1.9%)	5 (8.5%)	0.035
Primary bacteraemia	25 (15.6%)	5 (8.5%)	0.249
Other	8 (5.0%)	-	0.154
Unknown origin	31 (19.4%)	23 (40.0%)	0.006
Severity of sepsis and delay of anti-infective therapy			
Bacteremia/ sepsis	115 (71.9%)	23 (39.0%)	<0.001
Severe sepsis/ septic shock	45 (28.1%)	36 (61.0%)	
Delayed anti-infective treatment (days)	1 (0;3)	0 (0;2)	0.116
ESBL Genotype			
No ESBL genotype	4 (2.5%)	3 (5.1%)	0.390
CTX-M-1	38 (23.8%)	1 (1.7%)	<0.001
CTX-M-14	13 (8.1%)	1 (1.7%)	0.119
CTX-M-15	68 (42.5%)	30 (50.8%)	0.287
CTX-M-2	1 (0.6%)	-	1.000
CTX-M-2/97	2 (1.3%)	-	1.000
CTX-M-3	3 (1.9%)	3 (5.1%)	0.347
CTX-M-32	2 (1.3%)	-	1.000
CTX-M-55	1 (0.6%)	1 (1.7%)	0.467

CTX-M-61	1 (0.6%)	-	1.000
SHV-12	2 (1.3%)	-	1.000
SHV-2	-	1 (1.7%)	0.269
SHV-5	-	13 (22%)	<0.001
SHV-7	-	1 (1.7%)	0.269
TEM-12	1 (0.6%)	-	1.000
TEM-52	4 (2.5%)	-	0.576
Unknown (not available for genotype analysis)	20 (12.5%)	5 (8.5%)	0.481

Underlying conditions

Heart disease	27 (16.9%)	12 (20.3%)	0.555
Vascular disease	36 (22.5%)	9 (15.3%)	0.264
Neurologic disease	14 (8.8%)	7 (11.9%)	0.605
Chronic pulmonary disease	22 (13.8%)	14 (23.7%)	0.099
Connective tissue disease	3 (1.9%)	-	0.565
Ulcer disease	7 (4.4%)	1 (1.7%)	0.686
Liver disease	29 (18.1%)	12 (20.3%)	0.700
Diabetes mellitus	37 (23.1%)	17 (28.8%)	0.383
Moderate/ severe renal disease	72 (45.0%)	34 (57.6%)	0.127
Cancer/ immunological disease	65 (40.6%)	22 (37.3%)	0.756

Continuous parameter are displayed as median (interquartile range), categorical parameter as number (percentage). ESBL, extended-spectrum beta-lactamase.

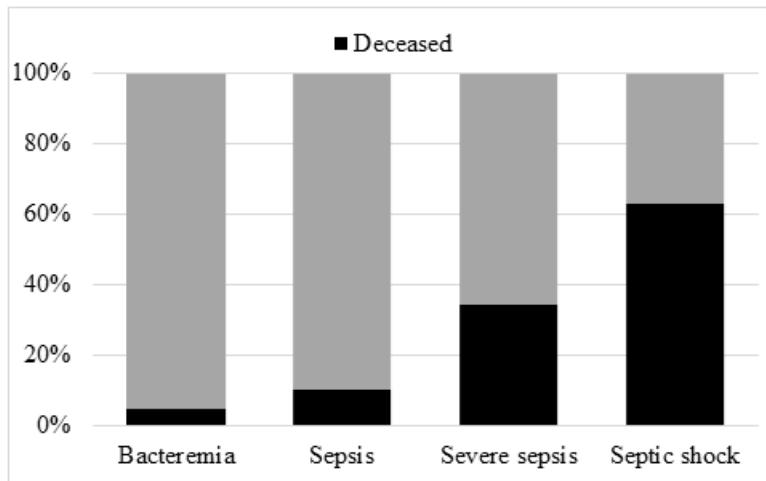

Fig 1. Severity of sepsis in relation to mortality rate

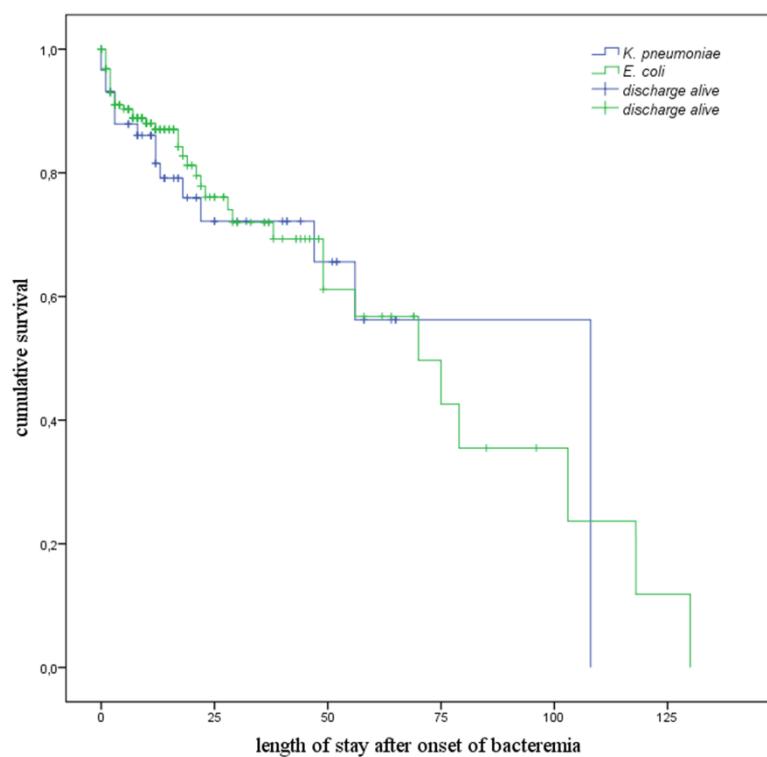

Fig 2. Kaplan Meier plot for cumulative survival associated with length of stay after onset of bacteremia stratified by infecting organism ESBL-positive -*E. coli* vs. -*K. pneumoniae*.

7 Lebenslauf

Mein Lebenslauf wird aus datenschutzrechtlichen Gründen in der elektronischen Version meiner Arbeit nicht veröffentlicht.

8 Publikationsliste

Sepsis Caused by Extended-Spectrum Beta-Lactamase (ESBL)-Positive *K. pneumoniae* and *E. coli*: Comparison of Severity of Sepsis, Delay of Anti-Infective Therapy and ESBL Genotype.

Sakellariou C, Gürntke S, Steinmetz I, Kohler C, Pfeifer Y, Gastmeier P, Schwab F, Kola A, Deja M, Leistner R.

PLoS One. 2016 Jul 21;11(7):e0158039. doi:
10.1371/journal.pone.0158039. ECollection 2016.

Impact-Factor (2016): 3,05

Bloodstream infection due to extended-spectrum beta-lactamase (ESBL)-positive *K. pneumoniae* and *E. coli*: an analysis of the disease burden in a large cohort.

Leistner R, Gürntke S, Sakellariou C, Denkel LA, Bloch A, Gastmeier P, Schwab F.

Infection. 2014 Dec;42(6):991-7. doi: 10.1007/s15010-014-0670-9. Epub 2014 Aug 7.

Impact-Factor (2014): 2,618

Mortality and molecular epidemiology associated with extended-spectrum β-lactamase production in *Escherichia coli* from bloodstream infection.

Leistner R, Sakellariou C, Gürntke S, Kola A, Steinmetz I, Kohler C, Pfeifer Y, Eller C, Gastmeier P, Schwab F.

Infect Drug Resist. 2014 Mar 13;7:57-62. doi: 10.2147/IDR.S56984.
ECollection 2014.

9 Danksagung

Ich bedanke mich bei meinen Eltern, die stets an mich glaubten und mir diesen Weg ermöglicht haben. Ebenfalls bedanke ich mich bei Prof. Gastmeier und allen Mitarbeitern des Instituts für Hygiene und Umweltmedizin der Charité Berlin für die Unterstützung und die Möglichkeit, diese Arbeit zu erstellen. Ich danke allen Mitautoren für die angenehme Zusammenarbeit. Zuletzt gilt mein besonderer Dank Dr. Leistner für sein unermüdliches Engagement, seine Geduld und die besondere Freundschaft, die über die Jahre zwischen uns entstanden ist.
