# THICKNESS OF THE UNIT SPHERE, $\ell_{1}$-TYPES, AND THE ALMOST DAUGAVET PROPERTY 

VLADIMIR KADETS, VARVARA SHEPELSKA AND DIRK WERNER

#### Abstract

We study those Banach spaces $X$ for which $S_{X}$ does not admit a finite $\varepsilon$-net consisting of elements of $S_{X}$ for any $\varepsilon<2$. We give characterisations of this class of spaces in terms of $\ell_{1}$-type sequences and in terms of the almost Daugavet property. The main result of the paper is: a separable Banach space $X$ is isomorphic to a space from this class if and only if $X$ contains an isomorphic copy of $\ell_{1}$.

## 1. Introduction

For a Banach space $X, \mathrm{R}$. Whitley [9] introduced the following parameter, called thickness, which is essentially the inner measure of non-compactness of the unit sphere $S_{X}$ :

$$
T(X)=\inf \left\{\varepsilon>0 \text { : there exists a finite } \varepsilon \text {-net for } S_{X} \text { in } S_{X}\right\},
$$

or equivalently, $T(X)$ is the infimum of those $\varepsilon$ such that the unit sphere of $X$ can be covered by a finite number of balls with radius $\varepsilon$ and centres in $S_{X}$. He showed in the infinite dimensional case that $1 \leq T(X) \leq 2$, and in particular that $T(C(K))=1$ if $K$ has isolated points and $T(C(K))=2$ if not.

In this paper we concentrate on the spaces with $T(X)=2$. Our main results are the following; $B_{X}$ denotes the closed unit ball of $X$.

Theorem 1.1. For a separable Banach space $X$ the following conditions are equivalent:
(a) $T(X)=2$;
(b) there is a sequence $\left(e_{n}\right) \subset B_{X}$ such that for every $x \in X$

$$
\lim _{n \rightarrow \infty}\left\|x+e_{n}\right\|=\|x\|+1 ;
$$

(c) there is a norming subspace $Y \subset X^{*}$ such that the equation

$$
\begin{equation*}
\|\operatorname{Id}+T\|=1+\|T\| \tag{1.1}
\end{equation*}
$$

holds true for every rank-one operator $T: X \rightarrow X$ of the form $T=$ $y^{*} \otimes x$, where $x \in X$ and $y^{*} \in Y$.

Theorem 1.2. A separable Banach space $X$ can be equivalently renormed to have thickness $T(X)=2$ if and only if $X$ contains an isomorphic copy of $\ell_{1}$.

Recall that a subspace $Y \subset X^{*}$ is said to be norming (or 1-norming) if for every $x \in X$

$$
\sup _{y^{*} \in S_{Y}}\left|y^{*}(x)\right|=\|x\| .
$$

$Y$ is norming if and only if $S_{Y}$ is weak* dense in $B_{X^{*}}$.
Condition (b) of Theorem 1.1 links our investigations to the theory of types [7]. Recall that a type on a separable Banach space $X$ is a function of the form

$$
\tau(x)=\lim _{n \rightarrow \infty}\left\|x+e_{n}\right\|
$$

for some bounded sequence $\left(e_{n}\right)$. In [7] the notion of an $\ell_{1}$-type is defined by means of convolution of types; a special instance of this is a type generated by a sequence $\left(e_{n}\right)$ satisfying

$$
\begin{equation*}
\tau(x)=\lim _{n \rightarrow \infty}\left\|x+e_{n}\right\|=\|x\|+1 \tag{1.2}
\end{equation*}
$$

To simplify notation let us call a type like this a canonical $\ell_{1}$-type and a sequence $\left(e_{n}\right) \subset B_{X}$ satisfying (1.2) a canonical $\ell_{1}$-type sequence.

Condition (c) links our investigations to the theory of Banach spaces with the Daugavet property introduced in [5] and developed further for instance in the papers [1] [2], [3], [6]; see also the survey [8]. We will say that a Banach space $X$ has the Daugavet property with respect to $Y(X \in \operatorname{DPr}(Y))$ if the Daugavet equation (1.1) holds true for every rank-one operator $T: X \rightarrow X$ of the form $T=y^{*} \otimes x$, where $x \in X$ and $y^{*} \in Y$, and it has the almost Daugavet property or is an almost Daugavet space if it has $\operatorname{DPr}(Y)$ for some norming subspace $Y \subset X^{*}$. This definition is a generalization (introduced in [4]) of the by now well-known Daugavet property of [5], which is $\operatorname{DPr}(Y)$ with $Y=X^{*}$.
In this language Theorem 1.2 says, by Theorem 1.1, that a separable Banach space can be renormed to have the almost Daugavet property if and only if it contains a copy of $\ell_{1}$.

In Section 2 we present a characterisation of almost Daugavet spaces in terms of $\ell_{1}$-sequences of the dual. The proofs of Theorems 1.1 and 1.2 will be given in Sections 3 and 4 .

The following lemma is the main technical prerequisite that we use; it is the analogue of [5, Lemma 2.2]. Up to part (v) it was proved in [4]; however, (v) follows along the same lines. By a slice of $B_{X}$ we mean a set of the form

$$
S\left(y^{*}, \varepsilon\right)=\left\{x \in B_{X}: y^{*}(x) \geq 1-\varepsilon\right\}
$$

for some $y^{*} \in S_{X^{*}}$ and some $\varepsilon>0$, and a weak ${ }^{*}$ slice $S(y, \varepsilon)$ of the dual ball $B_{X^{*}}$ is a particular case of slice, generated by element $y \in S_{X} \subset X^{* *}$.

Lemma 1.3. If $Y$ is a norming subspace of $X^{*}$, then the following assertions are equivalent.
(i) $X$ has the Daugavet property with respect to $Y$.
(ii) For every $x \in S_{X}$, for every $\varepsilon>0$, and for every $y^{*} \in S_{Y}$ there is some $y \in S\left(y^{*}, \varepsilon\right)$ such that

$$
\begin{equation*}
\|x+y\| \geq 2-\varepsilon . \tag{1.3}
\end{equation*}
$$

(iii) For every $x \in S_{X}$, for every $\varepsilon>0$, and for every $y^{*} \in S_{Y}$ there is a slice $S\left(y_{1}^{*}, \varepsilon_{1}\right) \subset S\left(y^{*}, \varepsilon\right)$ with $y_{1}^{*} \in S_{Y}$ such that (1.3) holds for every $y \in S\left(y^{*}, \varepsilon_{1}\right)$.
(iv) For every $x^{*} \in S_{Y}$, for every $\varepsilon>0$, and for every weak* slice $S(x, \varepsilon)$ of the dual ball $B_{X^{*}}$ there is some $y^{*} \in S(x, \varepsilon)$ such that $\left\|x^{*}+y^{*}\right\| \geq 2-\varepsilon$.
(v) For every $x^{*} \in S_{Y}$, for every $\varepsilon>0$, and for every weak* slice $S(x, \varepsilon)$ of the dual ball $B_{X^{*}}$ there is another weak* slice $S\left(x_{1}, \varepsilon_{1}\right) \subset S(x, \varepsilon)$ such that $\left\|x^{*}+y^{*}\right\| \geq 2-\varepsilon$ for every $y^{*} \in S\left(x_{1}, \varepsilon_{1}\right)$.

## 2. A characterisation of almost Daugavet spaces by means of $\ell_{1}$-SEQUENCES IN THE DUAL

For the sake of easy notation we introduce two definitions.
Definition 2.1. Let $E$ be subspace of a Banach space $F$ and $\varepsilon>0$. An element $e \in B_{F}$ is said to be ( $\varepsilon, 1$ )-orthogonal to $E$ if for every $x \in E$ and $t \in \mathbb{R}$

$$
\begin{equation*}
\|x+t e\| \geq(1-\varepsilon)(\|x\|+|t|) . \tag{2.1}
\end{equation*}
$$

Definition 2.2. Let $E$ be a Banach space. A sequence $\left\{e_{n}\right\}_{n \in \mathbb{N}} \subset B_{E} \backslash\{0\}$ is said to be an asymptotic $\ell_{1}$-sequence if there is a sequence of numbers $\varepsilon_{n}>0$ with $\prod_{n \in \mathbb{N}}\left(1-\varepsilon_{n}\right)>0$ such that $e_{n+1}$ is $\left(\varepsilon_{n}, 1\right)$-orthogonal to $Y_{n}:=\operatorname{lin}\left\{e_{1}, \ldots, e_{n}\right\}$ for every $n \in \mathbb{N}$.

Evidently every asymptotic $\ell_{1}$-sequence is $1 / \prod_{n \in \mathbb{N}}\left(1-\varepsilon_{n}\right)$-equivalent to the unit vector basis in $\ell_{1}$, and moreover every element of the unit sphere of $E_{m}:=\operatorname{lin}\left\{e_{k}\right\}_{k=m+1}^{\infty}$ is $\left(1-\prod_{n \geq m}\left(1-\varepsilon_{n}\right), 1\right)$-orthogonal to $Y_{m}$ for every $m \in \mathbb{N}$.

The following lemma is completely analogous to [5, Lemma 2.8]; instead of [5, Lemma 2.1] it uses (v) of Lemma 1.3. So we state it without proof.
Lemma 2.3. Let $Y$ be a norming subspace of $X^{*}, X \in \operatorname{DPr}(Y)$, and let $Y_{0} \subset Y$ be a finite-dimensional subspace. Then for every $\varepsilon_{0}>0$ and every weak* slice $S\left(x_{0}, \varepsilon_{0}\right)$ of $B_{X^{*}}$ there is another weak ${ }^{*}$ slice $S\left(x_{1}, \varepsilon_{1}\right) \subset S\left(x_{0}, \varepsilon_{0}\right)$ of $B_{X^{*}}$ such that every element $e^{*} \in S\left(x_{1}, \varepsilon_{1}\right)$ is $\left(\varepsilon_{0}, 1\right)$-orthogonal to $Y_{0}$. In particular there is an element $e_{1}^{*} \in S\left(x_{0}, \varepsilon_{0}\right) \cap S_{Y}$ which is $\left(\varepsilon_{0}, 1\right)$-orthogonal to $Y_{0}$.

We need one more definition.
Definition 2.4. A sequence $\left\{e_{n}^{*}\right\}_{n \in \mathbb{N}} \subset B_{X^{*}}$ is said to be double-norming if $\operatorname{lin}\left\{e_{k}^{*}\right\}_{k=n}^{\infty}$ is norming for every $n \in \mathbb{N}$.

Here is the main result of this section.
Theorem 2.5. A separable Banach space $X$ is an almost Daugavet space if and only if $X^{*}$ contains a double-norming asymptotic $\ell_{1}$-sequence.

Proof. First we prove the "if" part. Let $\left\{e_{n}^{*}\right\}_{n \in \mathbb{N}} \subset B_{X^{*}}$ be a double-norming asymptotic $\ell_{1}$-sequence, and let $\varepsilon_{n}>0$ with $\prod_{n \in \mathbb{N}}\left(1-\varepsilon_{n}\right)>0$ be such that $e_{n+1}^{*}$ is ( $\varepsilon_{n}, 1$ )-orthogonal to $Y_{n}:=\operatorname{lin}\left\{e_{1}^{*}, \ldots, e_{n}^{*}\right\}$ for every $n \in \mathbb{N}$. Let us prove that $X$ has the Daugavet property with respect to $Y=\overline{\operatorname{lin}}\left\{e_{n}^{*}\right\}_{n \in \mathbb{N}}$ where the closure is meant in the norm topology. To do this let us apply (iv) of Lemma 1.3.

Fix an $x^{*} \in S_{Y}$, an $\varepsilon>0$ and a weak ${ }^{*}$ slice $S(x, \varepsilon)$ of the dual ball $B_{X^{*}}$. Denote in addition to $Y_{m}=\operatorname{lin}\left\{e_{1}^{*}, \ldots, e_{m}^{*}\right\}, E_{m}:=\operatorname{lin}\left\{e_{k}^{*}\right\}_{k=m+1}^{\infty}$. Using the definition of $Y$ select an $m \in \mathbb{N}$ and an $x_{m}^{*} \in Y_{m}$ such that $\left\|x^{*}-x_{m}^{*}\right\|<\varepsilon / 2$ and $\prod_{n \geq m}\left(1-\varepsilon_{n}\right)>1-\varepsilon / 2$. Since $E_{m}$ is norming, there is a $y^{*} \in S(x, \varepsilon) \cap S_{E_{m}}$. Taking into account that every element of the unit sphere of $E_{m}$ is $(\varepsilon / 2,1)$-orthogonal to $Y_{m}$ we obtain

$$
\left\|x^{*}+y^{*}\right\| \geq\left\|x_{m}^{*}+y^{*}\right\|-\left\|x^{*}-x_{m}^{*}\right\| \geq 2-\varepsilon .
$$

For the "only if" part we proceed as follows. First we fix a sequence of numbers $\varepsilon_{n}>0$ with $\prod_{n \in \mathbb{N}}\left(1-\varepsilon_{n}\right)>0$ and a dense sequence $\left(x_{n}\right)$ in $S_{X}$. We can choose these $x_{n}$ in such a way that each of them appears in the sequence $\left(x_{n}\right)$ infinitely many times. Assume now that $X \in \operatorname{DPr}(Y)$ with respect to a norming subspace $Y \subset X^{*}$. Starting with $Y_{0}=\{0\}, \varepsilon_{0}=1$ and applying Lemma 2.3 step-by-step we can construct a sequence $\left\{e_{n}^{*}\right\}_{n \in \mathbb{N}} \subset S_{Y}$ in such a way that each $e_{n+1}^{*}$ belongs to $S\left(x_{n}, \varepsilon_{n}\right)$ and is $\left(\varepsilon_{n}, 1\right)$-orthogonal to $Y_{n}$, where $Y_{n}=\operatorname{lin}\left\{e_{1}^{*}, \ldots, e_{n}^{*}\right\}$ as before. This inductive construction ensures that the $e_{n}^{*}, n \in \mathbb{N}$ form an asymptotic $\ell_{1}$-sequence. On the other hand this sequence meets every slice $S\left(x_{n}, \varepsilon_{n}\right)$ infinitely many times, and this implies by density of $\left(x_{n}\right)$ that $\left(e_{n}^{*}\right)$ is double-norming.

In Corollary 3.4 we shall observe a somewhat more pleasing version of the last result.

We conclude the section with two examples.
Proposition 2.6. $\ell_{1}$ is an almost Daugavet space.
Proof. To prove this statement we will construct a double-norming asymptotic $\ell_{1}$-sequence $\left(f_{n}\right) \subset \ell_{\infty}=\left(\ell_{1}\right)^{*}$. At first consider a sequence $\left(g_{n}\right) \subset \ell_{\infty}$ of elements $g_{n}=\left(g_{n, j}\right)_{j \in \mathbb{N}}$ with all $g_{n, j}= \pm 1$ satisfying the following independence condition: for arbitrary finite collections $\alpha_{s}= \pm 1, s=1, \ldots, n$, the set of those $j$ that $g_{s, j}=\alpha_{s}$ for all $s=1, \ldots, n$ is infinite (for instance, put $g_{s, j}:=r_{s}\left(t_{j}\right)$, where the $r_{s}$ are the Rademacher functions and $\left(t_{j}\right)_{j \in \mathbb{N}}$ is a fixed sequence of irrationals that is dense in $[0,1])$. These $g_{n}, n \in \mathbb{N}$ form an isometric $\ell_{1}$-sequence, and moreover if one changes a finite number of coordinates in each of the $g_{n}$ to some other $\pm 1$, the independence condition will survive, so the modified sequence will still be an isometric $\ell_{1}$-sequence.

Now let us define the vectors $f_{n}=\left(f_{n, j}\right)_{j \in \mathbb{N}}, f_{n, j}= \pm 1$, in such a way that for $k=1,2, \ldots$ and $n=2^{k}+1,2^{k}+2, \ldots, 2^{k+1}$ the vectors $\left(f_{n, j}\right)_{j=1}^{k} \in \ell_{\infty}^{(k)}$ run over all extreme points of the unit ball of $\ell_{\infty}^{(k)}$, i.e., over all possible $k$-tuples of $\pm 1$; for the remaining values of indices we put $f_{n, j}=g_{n, j}$. As we have already remarked, the $f_{n}$ form an isometric $\ell_{1}$-sequence. Moreover, for every $k \in \mathbb{N}$ the restrictions of the $f_{n}$ to the first $k$ coordinates form a double-norming sequence over $\ell_{1}^{(k)}$, so $\left(f_{n}\right)_{n \in \mathbb{N}}$ is a double-norming sequence over $\ell_{1}$.

Since $\ell_{\infty}$ is isomorphic to $L_{\infty}[0,1]$, which has the Daugavet property, $\ell_{\infty}$ can be equivalently renormed to possess the Daugavet property. Let us show that in the original norm it is not even an almost Daugavet space.

Proposition 2.7. $\ell_{\infty}$ is not an almost Daugavet space.
Proof. Let us call a functional $y^{*} \in X^{*}$ a Daugavet functional if

$$
\left\|\operatorname{Id}+y^{*} \otimes x\right\|=1+\left\|y^{*} \otimes x\right\| \quad \text { for every } x \in X
$$

Let $X=\ell_{\infty}$ and $y^{*}=\left(y_{n}^{*}\right) \in \ell_{1} \subset\left(\ell_{\infty}\right)^{*}$. If $y^{*} \neq 0$, then it is not a Daugavet functional. Indeed, assume $\left\|y^{*}\right\|=1$. Pick an index $r$ such that $y_{r}^{*}=\alpha \neq 0$; let's say $r=1$ for simplicity. If $\alpha>0$, let $x=-e_{1}$ and $\varepsilon=\alpha / 2$. If $y^{*}$ were a Daugavet functional, then (see Lemma 1.3) for some $z=\left(z_{n}\right) \in \ell_{\infty},\|z\|=1$,

$$
y^{*}(z) \geq 1-\varepsilon, \quad\|z+x\| \geq 2-\varepsilon .
$$

Hence, putting $u=1-z_{1}$

$$
1-\varepsilon \leq y^{*}(z) \leq \alpha z_{1}+\sum_{n=2}^{\infty}\left|y_{n}^{*} \|\left|z_{n}\right| \leq \sum_{n=1}^{\infty}\right| y_{n}^{*} \mid-u \alpha
$$

so that $u \leq \varepsilon / \alpha=1 / 2$ and $z_{1} \geq 1 / 2$. On the other hand, $\|z+x\| \geq 2-\varepsilon$ implies that $\left|z_{1}-1\right| \geq 2-\varepsilon \geq 3 / 2$ which is impossible for $1 / 2 \leq z_{1} \leq 1$. The case $\alpha<0$ is treated in the same way.

Now, each $y^{*} \in\left(\ell_{\infty}\right)^{*}$ can be decomposed as

$$
y^{*}=v^{*}+w^{*} \in \ell_{1} \oplus\left(c_{0}\right)^{\perp}, \quad\left\|y^{*}\right\|=\left\|v^{*}\right\|+\left\|w^{*}\right\| .
$$

Hence if $y^{*}$ is a Daugavet functional, so is $v^{*}$, which implies $v^{*}=0$ and $y^{*} \in\left(c_{0}\right)^{\perp}$. But $\left(c_{0}\right)^{\perp}$ is not norming, and neither is any of its subspaces.

Consequently, $\ell_{\infty}$ fails the almost Daugavet property.

## 3. Proof of Theorem 1.1

We will accomplish the proof of Theorem 1.1 by means of the following propositions.

The following fact applied for separable spaces is equivalent to implication (c) $\Rightarrow$ (a) of Theorem 1.1.

Proposition 3.1. Every almost Daugavet space $X$ has thickness $T(X)=2$.
Proof. Let $Y \subset X^{*}$ be a norming subspace with respect to which $X \in$ $\mathrm{D} \operatorname{Pr}(Y)$. According to the definition of $T(X)$ we have to show that for every $\varepsilon_{0}>0$ there is no finite $\left(2-\varepsilon_{0}\right)$-net of $S_{X}$ consisting of elements of $S_{X}$. In other words we must demonstrate that for every collection $\left\{x_{1}, \ldots, x_{n}\right\} \subset$ $S_{X}$ there is a $y_{0} \in S_{X}$ with $\left\|x_{k}-y_{0}\right\|>2-\varepsilon_{0}$ for all $k=1, \ldots, n$. But this is an evident corollary of Lemma 1.3(iii): starting with an arbitrary $y_{0}^{*} \in S_{Y^{*}}$ and applying (iii) we can construct recursively elements $y_{k}^{*} \in S_{Y^{*}}$ and reals $\varepsilon_{k} \in(0, \varepsilon), k=1, \ldots, n$, in such a way that $S\left(y_{k}^{*}, \varepsilon_{k}\right) \subset S\left(y_{k-1}^{*}, \varepsilon_{k-1}\right)$ and

$$
\left\|\left(-x_{k}\right)+y\right\|>2-\varepsilon_{0}
$$

for every $y \in S\left(y_{k}^{*}, \varepsilon_{k}\right)$. Since $S\left(y_{n}^{*}, \varepsilon_{n}\right)$ is the smallest of the slices constructed, every norm-one element of $S\left(y_{n}^{*}, \varepsilon_{n}\right)$ can be taken as the $y_{0}$ we need.

Let us now turn to the implication $(\mathrm{a}) \Rightarrow(\mathrm{b})$ of Theorem 1.1.
Proposition 3.2. If $T(X)=2$ and $X$ is separable, then $X$ contains a canonical $\ell_{1}$-type sequence.

Proof. Fix a dense countable set $A=\left\{a_{n}: n \in \mathbb{N}\right\} \subset S_{X}$ and a null-sequence $\left(\varepsilon_{n}\right)$ of positive reals. Since for every $n \in \mathbb{N}$ the $n$-point set $\left\{-a_{1}, \ldots,-a_{n}\right\}$ is not a $\left(2-\varepsilon_{n}\right)$-net of $S_{X}$ there is an $e_{n} \in S_{X}$ with $\left\|e_{n}-\left(-a_{k}\right)\right\|>2-\varepsilon_{n}$ for all $k=1, \ldots, n$. The constructed sequence $\left(e_{n}\right)$ satisfies for every $k \in \mathbb{N}$ the condition

$$
\lim _{n \rightarrow \infty}\left\|a_{k}+e_{n}\right\|=\left\|a_{k}\right\|+1=2
$$

By the density of $A$ in $S_{X}$ and a standard convexity argument (cf. e.g. [8, page 78]) this yields that $\left(e_{n}\right)$ is a canonical $\ell_{1}$-type sequence.

It remains to prove the implication $(\mathrm{b}) \Rightarrow(\mathrm{c})$ of Theorem 1.1.
Proposition 3.3. A separable Banach space $X$ containing a canonical $\ell_{1}$ type sequence is an almost Daugavet space.

Proof. We will use Theorem 2.5. Fix an increasing sequence of finite-dimensional subspaces $E_{1} \subset E_{2} \subset E_{3} \subset \ldots$ whose union is dense in $X$. Also, fix sequences $\varepsilon_{n} \searrow 0$ and $\delta_{n}>0$ such that for all $n$

$$
\begin{equation*}
\prod_{k=n}^{\infty}\left(1-\delta_{k}\right) \geq 1-\varepsilon_{n} \tag{3.1}
\end{equation*}
$$

Passing to a subsequence if necessary we can find a canonical $\ell_{1}$-type sequence $\left(e_{n}\right)$ satisfying the following additional condition: For every $x \in$ $\operatorname{lin}\left(E_{n} \cup\left\{e_{1}, \ldots, e_{n}\right\}\right)$ and every $\alpha \in \mathbb{R}$ we have

$$
\begin{equation*}
\left\|x+\alpha e_{n+1}\right\| \geq\left(1-\delta_{n}\right)(\|x\|+|\alpha|) \tag{3.2}
\end{equation*}
$$

Then we have for every $x \in E_{n}$ and every $y=\sum_{k=n+1}^{M} a_{k} e_{k}$ by (3.1) and (3.2)

$$
\begin{equation*}
\|x+y\| \geq\left(1-\varepsilon_{n}\right)\|x\|+\sum_{k=n+1}^{M}\left(1-\varepsilon_{k-1}\right)\left|a_{k}\right| \tag{3.3}
\end{equation*}
$$

Fix a dense sequence $\left(x_{n}\right)$ in $S_{X}$ such that $x_{n} \in E_{n}$ and every element of the range of the sequence is attained infinitely often, that is for each $m \in \mathbb{N}$ the set $\left\{n: x_{n}=x_{m}\right\}$ is infinite. Finally, fix an "independent" sequence $\left(g_{n}\right) \subset \ell_{\infty}, g_{n, j}= \pm 1$, as in the proof of Proposition 2.6.

Now we are ready to construct a double-norming asymptotic $\ell_{1}$-sequence $\left(f_{n}^{*}\right) \subset X^{*}$. First we define $\tilde{f}_{n}^{*}$ on $F_{n}:=\operatorname{lin}\left\{x_{n}, e_{n+1}, e_{n+2}, \ldots\right\}$ by

$$
\begin{align*}
\tilde{f}_{n}^{*}\left(x_{n}\right) & =1-\varepsilon_{n}  \tag{3.4}\\
\tilde{f}_{n}^{*}\left(e_{k}\right) & =\left(1-\varepsilon_{k-1}\right) g_{n, k} \quad(\text { if } k>n) \tag{3.5}
\end{align*}
$$

By (3.3), $\left\|\tilde{f}_{n}^{*}\right\| \leq 1$, and indeed $\left\|\tilde{f}_{n}^{*}\right\|=1$ by (3.5). Define $f_{n}^{*} \in X^{*}$ to be a Hahn-Banach extension of $\tilde{f}_{n}^{*}$. Condition (3.4) and the choice of $\left(x_{n}\right)$ ensure that $\left(f_{n}^{*}\right)$ is double-norming. Let us show that it is an isometric $\ell_{1}$-basis. Indeed, due to our definition of an "independent" sequence, for an arbitrary
finite collection $A=\left\{a_{1}, \ldots, a_{n}\right\}$ of non-zero coefficients the set $J_{A}$ of those $j>n$ that $g_{s, j}=\operatorname{sign} a_{s}, s=1, \ldots, n$, is infinite. So by (3.5)

$$
\left\|\sum_{s=1}^{n} a_{s} f_{s}^{*}\right\| \geq \sup _{j \in J_{A}}\left(\sum_{s=1}^{n} a_{s} f_{s}^{*}\right) e_{j}=\sup _{j \in J_{A}}\left(1-\varepsilon_{j-1}\right) \sum_{s=1}^{n}\left|a_{s}\right|=\sum_{s=1}^{n}\left|a_{s}\right|
$$

Since we have constructed an isometric $\ell_{1}$-basis in the last proof, we have obtained the following version of Theorem 2.5.

Corollary 3.4. A separable Banach space $X$ is an almost Daugavet space if and only if $X^{*}$ contains a double-norming isometric $\ell_{1}$-sequence.

## 4. Proof of Theorem 1.2

We start with two lemmas.
Lemma 4.1. Let $X$ be a linear space, $\left(e_{n}\right) \subset X$, and let $p$ be a seminorm on $X$. Assume that $\left(e_{n}\right)$ is an isometric $\ell_{1}$-basis with respect to $p$, i.e., $p\left(\sum_{k=1}^{n} a_{k} e_{k}\right)=\sum_{k=1}^{n}\left|a_{k}\right|$ for all $a_{1}, a_{2}, \ldots \in \mathbb{R}$. Fix a free ultrafilter $\mathcal{U}$ on $\mathbb{N}$ and define

$$
p_{r}(x)=\mathcal{U}-\lim _{n} p\left(x+r e_{n}\right)-r
$$

for $x \in X$ and $r>0$. Then:
(a) $0 \leq p_{r}(x) \leq p(x)$ for all $x \in X$,
(b) $p_{r}(x)=p(x)$ for all $x \in \operatorname{lin}\left\{e_{1}, e_{2}, \ldots\right\}$,
(c) the map $x \mapsto p_{r}(x)$ is convex for each $r$,
(d) the map $r \mapsto p_{r}(x)$ is convex for each $x$,
(e) $p_{r}(t x)=t p_{r / t}(x)$ for each $t>0$.

Proof. The only thing that is not obvious is that $p_{r}$ is positive; note that (b) is a well-known property of the unit vector basis of $\ell_{1}$. Now, given $\varepsilon>0$ pick $n_{\varepsilon}$ such that

$$
p\left(x+r e_{n_{\varepsilon}}\right) \leq \mathcal{U}-\lim _{n} p\left(x+r e_{n}\right)+\varepsilon
$$

Then for each $n \neq n_{\varepsilon}$

$$
\begin{aligned}
p\left(x+r e_{n}\right) & =p\left(x+r e_{n_{\varepsilon}}+r\left(e_{n}-e_{n_{\varepsilon}}\right)\right) \\
& \geq 2 r-p\left(x+r e_{n_{\varepsilon}}\right) \\
& \geq 2 r-\mathcal{U}-\lim _{n} p\left(x+r e_{n}\right)-\varepsilon
\end{aligned}
$$

hence $2 \mathcal{U}-\lim _{n} p\left(x+r e_{n}\right) \geq 2 r-2 \varepsilon$ and $p_{r} \geq 0$.
Lemma 4.2. Assume the conditions of Lemma 4.1. Then the function $r \mapsto p_{r}(x)$ is decreasing for each $x$. The quantity

$$
\bar{p}(x):=\lim _{r \rightarrow \infty} p_{r}(x)=\inf _{r} p_{r}(x)
$$

satisfies (a)-(c) of Lemma 4.1 and moreover

$$
\begin{equation*}
\bar{p}(t x)=t \bar{p}(x) \quad \text { for } t>0, x \in X \tag{4.1}
\end{equation*}
$$

Proof. By Lemma 4.1(a) and (d), $r \mapsto p_{r}(x)$ is bounded and convex, hence decreasing. Therefore, $\bar{p}$ is well defined. Clearly, (4.1) follows from (e) above.

Since for separable spaces the condition $T(X)=2$ is equivalent to the presence of a canonical $\ell_{1}$-type sequence and a canonical $\ell_{1}$-type sequence evidently contains a subsequence equivalent to the canonical basis of $\ell_{1}$, to prove Theorem 1.2 it is sufficient to demonstrate the following:

Theorem 4.3. Let $X$ be a Banach space containing a copy of $\ell_{1}$. Then $X$ can be renormed to admit a canonical $\ell_{1}$-type sequence. Moreover if $\left(e_{n}\right) \subset$ $X$ is an arbitrary sequence equivalent to the canonical basis of $\ell_{1}$ in the original norm, then one can construct an equivalent norm on $X$ in such a way that $\left(e_{n}\right)$ is isometrically equivalent to the canonical basis of $\ell_{1}$ and $\left(e_{n}\right)$ forms a canonical $\ell_{1}$-type sequence in the new norm.

Proof. Let $Y$ be a subspace of $X$ isomorphic to $\ell_{1}$, and let $\left(e_{n}\right)$ be its canonical basis. To begin with, we can renorm $X$ in such a way that $Y$ is isometric to $\ell_{1}$ and $\left(e_{n}\right)$ is an isometric $\ell_{1}$-basis.

Let $\mathcal{P}$ be the family of all seminorms $\tilde{p}$ on $X$ that are dominated by the norm of $X$ and for which $\tilde{p}(y)=\|y\|$ for $y \in Y$. By Zorn's lemma, $\mathcal{P}$ contains a minimal element, say $p$. We shall argue that

$$
\begin{equation*}
\lim _{n \rightarrow \infty} p\left(x+e_{n}\right)=p(x)+1 \quad \forall x \in X \tag{4.2}
\end{equation*}
$$

To show this it is sufficient to prove that for every free ultrafilter $\mathcal{U}$ on $\mathbb{N}$

$$
\begin{equation*}
\mathcal{U}-\lim _{n} p\left(x+e_{n}\right)=p(x)+1 \quad \forall x \in X \tag{4.3}
\end{equation*}
$$

To this end associate to $p$ and $\mathcal{U}$ the functional $\bar{p}$ from Lemma 4.2. Note that $0 \leq \bar{p} \leq p$, but $\bar{p}$ need not be a seminorm. However,

$$
q(x)=\frac{\bar{p}(x)+\bar{p}(-x)}{2}
$$

defines a seminorm, and $q \leq p$. By Lemma 4.1(b) and by minimality of $p$ we get that

$$
\begin{equation*}
q(x)=p(x) \quad \forall x \in X \tag{4.4}
\end{equation*}
$$

Now, since $p(x) \geq \bar{p}(x)$ and $p(x)=p(-x) \geq \bar{p}(-x)$, (4.4) implies that $p(x)=$ $\bar{p}(x)$. Finally, by Lemma 4.1(a) and the definition of $\bar{p}$ we have $p(x)=p_{r}(x)$ for all $r>0$; in particular $p(x)=p_{1}(x)$, which is our claim (4.3).

To complete the proof of the theorem, consider

$$
\|x\|:=p(x)+\|[x]\|_{X / Y}
$$

this is the equivalent norm that we need. Indeed, clearly $\|x\|\|\leq 2\| x \|$. On the other hand, $\|x\| \geq \frac{1}{3}\|x\|$. To see this assume $\|x\|=1$. If $\|[x]\|_{X / Y} \geq \frac{1}{3}$, there is nothing to prove. If not, pick $y \in Y$ such that $\|x-y\|<\frac{1}{3}$. Then $p(y)=\|y\|>\frac{2}{3}$, and

$$
\|x\| \geq p(x) \geq p(y)-p(x-y)>\frac{2}{3}-\|x-y\|>\frac{1}{3} .
$$

Therefore, $\|$.$\| and |||.| |$ are equivalent norms, and
$\lim _{n \rightarrow \infty}\left\|x+e_{n}\right\|\left\|=\lim _{n \rightarrow \infty} p\left(x+e_{n}\right)+\right\|[x]\left\|_{X / Y}=p(x)+1+\right\|[x]\left\|_{X / Y}=\right\| x\| \|+1$
shows that $\left(e_{n}\right)$ is a canonical $\ell_{1}$-type sequence for the new norm.
