Two-dimensional  $p_x + ip_y$  topological superconductors host gapless Majorana edge modes, as well as Majorana bound states at the core of  $h/2e$  vortices. Here we construct a model realizing the fractional counterpart of this phase: a fractional chiral superconductor. Our model is composed of an array of coupled Rashba wires in the presence of strong interactions, Zeeman field, and proximity coupling to an  $s$ -wave superconductor. We define the filling factor as  $\nu = l_{\text{so}}n/4$ , where  $n$  is the electronic density and  $l_{\text{so}}$  is the spin-orbit length. Focusing on filling  $\nu = 1/m$ , with  $m$  being an odd integer, we obtain a tractable model which allows us to study the properties of the bulk and the edge. Using an  $\epsilon$ -expansion with  $m = 2 + \epsilon$ , we show that the bulk Hamiltonian is gapped and that the edge of the sample hosts a chiral  $\mathbb{Z}_{2m}$  parafermion theory with central charge  $c = \frac{2m-1}{m+1}$ . The tunneling density of states associated with this edge theory exhibits an anomalous energy dependence of the form  $\omega^{m-1}$ . Additionally, we show that  $\mathbb{Z}_{2m}$  parafermionic bound states reside at the cores of  $h/2e$  vortices. Upon constructing an appropriate Josephson junction in our system, we find that the current-phase relation displays a  $4\pi m$  periodicity, reflecting the underlying non-abelian excitations.

*Introduction.*— Much is nowadays known about topological states which can be understood from a non-interacting limit. In this limit, the topological states protected by time-reversal, particle-hole, and chiral symmetries have been classified [1, 2]. Beyond this celebrated periodic table, topological phases protected by other symmetries such as lattice symmetries [3–11], have also been thoroughly studied.

In contrast, strongly interacting topologically ordered phases which cannot be understood in the absence of interactions, have yet to be fully understood and classified. Since interactions stabilize these phases, their study generally requires non-perturbative methods. A relatively recent approach to this problem is the coupled-wires approach [12–32], in which a two-dimensional (2D) or three-dimensional (3D) topologically ordered phase is constructed from an array of coupled quantum wires. The available machinery for studying interacting one-dimensional (1D) systems plays a central role in allowing one to write exactly solvable or analytically tractable model systems realizing such non-trivial phases of matter.

In this work we employ this approach to study *fractional* chiral superconductors (FCSC) in 2D. FCSC phases were previously introduced, mostly from a field-theoretic point of view, in Refs. [33–35]. The coupled-wires approach provides us with a tractable model which admits direct study of the properties of such phases.

We begin by constructing a non-interacting  $p_x + ip_y$  topological superconductor (TSC). Following Ref. [15], this is done by placing an array of  $N$  non-interacting weakly-coupled Rashba wires in proximity to an  $s$ -wave superconductor and applying a Zeeman field. We then add the effects of interactions and show that a fractional chiral superconductor (FCSC) can emerge at fractional filling factors, defined through the spin-orbit length (see Eq. 2). The main observation that will allow us to construct a model realizing the strongly-interacting FCSC

FIG. 1: (a) A schematic view of the system we use to construct a two-dimensional fractional chiral superconductor (FCSC). The system is composed of an array of  $N$  weakly coupled wires with strong Rashba spin-orbit coupling. We demonstrate that the interplay of the Zeeman field, proximity to an  $s$ -wave superconductor, and strong interactions can result in FCSC phase with a chiral parafermion CFT at the edges of the sample and parafermionic bound states at the core of vortices. (b) A corbino geometry, used in order to study  $h/2e$  vortices and the anomalous Josephson effect. By connecting the internal and external parts with a superconducting wire, through which flux can be inserted, the relative phases between the two superconducting regions can be controlled. It is argued that in the quasi-one-dimensional regime this configuration is equivalent to the effective junction shown in Fig. 3f, leading to a  $4\pi m$ -periodic Josephson effect.

phase is that, at fractional filling factors, one can define new local fermionic operators, composed of an electron dressed by a particle-hole excitation, for which the effective filling factor becomes an integer. Exploiting this fact, we will use the results of Ref. [15] to write a  $p_x + ip_y$  topological superconductor in terms of the transformed fermions. Remarkably, in terms of the original fermions the resulting phase is a FCSC.

After constructing the model, we analyze it by mapping the low-energy theory of the individual wires at fractional fillings  $\nu = 1/m$  with odd  $m$  to a generalized Sine-Gordon model. Performing an  $\epsilon$ -expansion for  $m = 2 + \epsilon$ , we show that each wire can be tuned to

FIG. 2: The spectrum of an individual wire in the absence of interactions, Zeeman field, and proximity coupling. The dashed lines specify the chemical potentials corresponding to the situations  $\nu = 1$  and  $\nu = 1/3$ .

a  $\mathbb{Z}_{2m}$  parafermion multicritical point [36]. We then demonstrate that one can couple different wires in such a way that a chiral  $\mathbb{Z}_{2m}$  parafermion conformal field theory (CFT) is left on the edge (with  $m$  being an odd integer, i.e.,  $\mathbb{Z}_2, \mathbb{Z}_6, \mathbb{Z}_{10}, \dots$  theories). By construction, the resulting 2D model is topologically ordered.

Our model allows us to study the physical properties of the FCSC phase. By considering a Corbino geometry (see Fig. 3a), we are able to study  $h/2e$  vortices in the system. We show that these vortices host non-abelian parafermion zero-modes, by mapping our configuration to domain walls on the edge of a 2D fractional TI [37–39].

Finally, we examine the Josephson junction depicted in Fig. 1b, in which the superconductor stabilizing the FCSC is cut into two concentric annuli. In the quasi one-dimensional (thin annulus) regime, where coupling between the two edges is allowed, the radial Josephson current is shown to exhibit a  $4\pi m$ -periodicity as a function of the superconducting phase difference.

*Topological superconductor from an array of coupled wires.*— We start by reviewing the construction of a  $p_x + ip_y$  superconductor, presented in Ref. [15]. The starting point is an array of decoupled Rashba wires. Similar to Refs. [40, 41], each wire is subjected to a Zeeman field and proximity coupled to an  $s$ -wave superconductor,

$$H = \sum_n \int dx \bar{\psi}_n^\dagger(x) \left[ -\frac{(\partial_x - iuM\sigma_z)^2}{2M} - \mu + B\sigma_x \right] \bar{\psi}_n(x) + \int dx \left[ \Delta \psi_{n\uparrow}^\dagger(x) \psi_{n\downarrow}^\dagger(x) + \text{h.c.} \right]. \quad (1)$$

Here,  $\bar{\psi}_n = [\psi_{n\uparrow}(x) \ \psi_{n\downarrow}(x)]^T$ , where  $\psi_{ns}(x)$  represents the electron annihilation operator at wire number  $n$  with spin  $s$  (see Fig. 1a). The matrices  $\sigma_i$  are Pauli matrices operating on the spin degrees of freedom. The parameters  $u, B$ , and  $\Delta$  are the Rashba spin-orbit coupling (SOC), the Zeeman field, and the induced superconducting pairing potential, respectively.

Figure 2 presents the spectrum of a single wire in the absence of superconductivity and a Zeeman field ( $B = \Delta = 0$ ). We define the Fermi momentum  $k_F^0 = \sqrt{2M\mu}$  in the absence of SOC, and the shift  $k_{so} = Mu$  of the parabolas due to SOC. In terms of these, the filling fraction of the system is defined as

$$\nu = k_F^0/k_{so}. \quad (2)$$

To study the low energy physics, we linearize the spectrum near the Fermi level, and decompose the fermionic modes into right- and left-moving modes:

$$\psi_{ns}(x) = \psi_{nsR}(x) + \psi_{nsL}(x), \quad (3)$$

with  $\psi_{ns\rho}(x) = \psi_{ns\rho}^0(x)e^{ik_{s\rho}x}$ . Here,  $\psi_{ns\rho}^0$  are the low energy degrees of freedom near the Fermi momenta  $k_{s\rho} = \rho k_F^0 - sk_{so}$  (where  $\rho = \pm 1$  denotes a right/left moving mode).

The  $p_x + ip_y$  superconductor corresponds to  $\nu = 1$ . Focusing on the low-energy excitations for  $|\Delta - B| \ll B, \Delta$ , the Zeeman term  $H_B = \int dx [B\psi_{n\uparrow R}^\dagger(x)\psi_{n\downarrow L}(x) + \text{h.c.}]$  and the pairing term  $H_\Delta = \int dx \left\{ \Delta [\psi_{n\uparrow R}^\dagger(x)\psi_{n\downarrow L}^\dagger(x) + \psi_{n\uparrow L}^\dagger(x)\psi_{n\downarrow R}^\dagger(x)] + \text{h.c.} \right\}$  gap out the wires (see Fig. 2). Indeed, the second term in  $H_\Delta$  fully gaps the high-momentum degrees of freedom  $\psi_{n\uparrow L}$  and  $\psi_{n\downarrow R}$ , and the low-momentum degrees of freedom,  $\psi_{n\uparrow R}$  and  $\psi_{n\downarrow L}$ , are coupled by the Zeeman term  $H_B$  as well as the first term of  $H_\Delta$ . The fully gapped phases for  $\Delta > B$  and  $\Delta < B$  are topologically distinct - the first is a 1D trivial phase while the second is a topological superconductor. For  $B = \Delta$ , the inter-mode part of the Hamiltonian, given by  $H_\Delta + H_B$ , commutes with the operators

$$\alpha_n(x) = \psi_{n\uparrow R}(x) + \psi_{n\uparrow R}^\dagger(x), \\ \beta_n(x) = -i [\psi_{n\downarrow L}(x) - \psi_{n\downarrow L}^\dagger(x)], \quad (4)$$

so the system is gapless.

Tuning to this transition point, we introduce an inter-wire term of the form

$$H_\perp = it_\perp \sum_n \int dx \alpha_n(x) \beta_{n+1}(x). \quad (5)$$

This term arises naturally in the system of Fig. 1a due to a combination of inter-wire hopping, superconductivity, and spin-orbit interaction [15]. It gaps out the bulk degrees of freedom, yet it leaves the Majorana fields  $\beta_1(x)$  and  $\alpha_N(x)$  decoupled, thus stabilizing a  $p_x + ip_y$  TSC phase. This construction can be considered the anisotropic limit of the system studied by Refs. [42, 43]. While it relies on a fine-tuned relation between parameters, the resulting phase is independent of these assumptions, remaining qualitatively identical as long as the bulk gap remains open.

*Fractional chiral superconductors.*— To construct a FCSC phase at filling  $\nu = 1/m$ , we consider the effects of strong interactions, within a bosonized description of the 1D degrees of freedom. Using the standard Abelian bosonization technique, we describe the Hilbert space in terms of bosonic fields  $\phi_{ns\rho}$  via  $\psi_{ns\rho} \propto e^{i(\phi_{ns\rho} + k_{s\rho}x)}$ . The boson fields satisfy the commutation relations

$$[\phi_{ns\rho}(x), \phi_{n's'\rho'}(x')] = i\pi\rho\delta_{nn'}\delta_{ss'}\delta_{\rho\rho'} \text{sgn}(x - x') \\ + i\pi A_{ns\rho}^{n's'\rho'}, \quad (6)$$

where  $A_{ns\rho}^{n's'\rho'}$  takes the values  $\pm 1$  for any  $\{ns\rho\} \neq \{n's'\rho'\}$  and is antisymmetric with respect to the exchange  $\{ns\rho\} \leftrightarrow \{n's'\rho'\}$  (ensuring that the fermionic anti-commutation relations are satisfied).

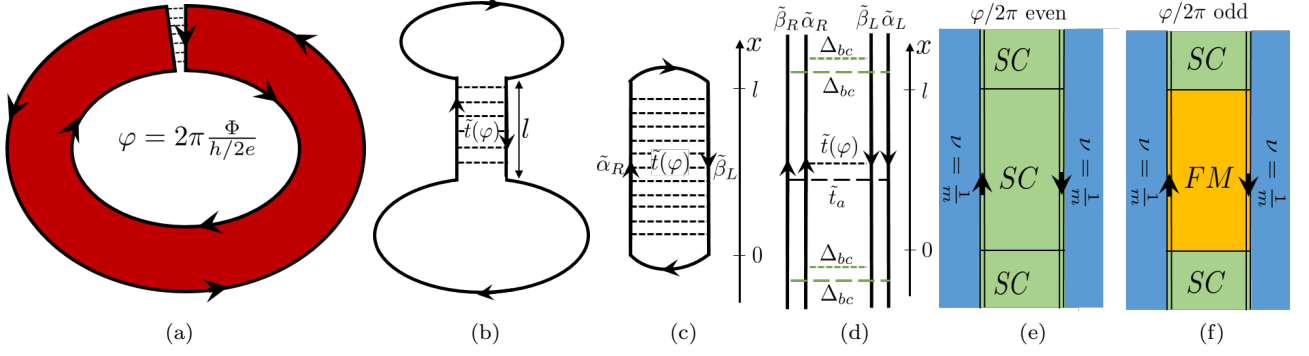

FIG. 3: A schematic depiction of the line of arguments used in order to identify the zero-modes localized at the center of  $h/2e$  vortices. (a) We start by placing our FCSC phase in an annular geometry, through which a magnetic flux may be inserted. Without altering the essential characteristics of the system, we cut a thin trench through the annulus. (b) As the presence of zero-modes should not depend on the precise geometry as long as the topological structure is preserved, we focus on the edge theory and fold our system inside-out to a bone shaped geometry. (c) The independence on the precise geometry allows us to shrink the outermost regions. (d) We examine an auxiliary model which has twice as many degrees of freedom, but whose low energy sector coincides with our model. We then show that the auxiliary model in (d) can be adiabatically deformed into a system composed of  $\nu = 1/m$  fractional quantum Hall edges coupled by ferromagnetic and superconducting terms. (e) If the flux  $\varphi$  is an even multiple of  $2\pi$ , we get effective superconducting term throughout the system, meaning there are no zero modes. (f) For odd multiples of  $2\pi$ , the superconductor in the physical region is replaced by a ferromagnet. The domain walls of the resulting configuration, representing the edges of the original configurations, give rise to parafermionic bound states [37–39].

For  $\nu = 1/m$ , it is useful to define new chiral fermion operators  $\tilde{\psi}_{n s \rho} = e^{i(\eta_{n s \rho} + q_{s \rho} x)}$ , with

$$\eta_{n s \rho} = \frac{m+1}{2} \phi_{n s \rho} - \frac{m-1}{2} \phi_{n s \bar{\rho}}. \quad (7)$$

The new fields,  $\tilde{\psi}_{n s \rho}$ , are fermionic, as evident from the commutation relations

$$[\eta_{n s \rho}(x), \eta_{n' s' \rho'}(x')] = i m \pi \rho \delta_{n n'} \delta_{s s'} \delta_{\rho \rho'} \text{sgn}(x - x') + i \pi \tilde{A}_{n s \rho}^{n' s' \rho'}, \quad (8)$$

where  $\tilde{A}_{n s \rho}^{n' s' \rho'}$  takes odd integer values for any  $\{n s \rho\} \neq \{n' s' \rho'\}$ , and is antisymmetric with respect to the exchange  $\{n s \rho\} \leftrightarrow \{n' s' \rho'\}$ . The  $\tilde{\psi}_{n s \rho}$  fields carry momenta  $q_{s \rho} = \frac{m+1}{2} k_{s \rho} - \frac{m-1}{2} k_{s \bar{\rho}}$ .

Note that the momenta  $q_{s \rho}$  carried by the new fields  $\tilde{\psi}_{n s \rho}$  match those of a  $\nu = 1$  wire. In particular, the operators  $\tilde{\psi}_{n \uparrow R}$  and  $\tilde{\psi}_{n \downarrow L}$  now have vanishing oscillatory components, allowing us to couple them in various ways without breaking translational symmetry.

Once the Zeeman term is dressed by intra-wire  $2k_F$ -interactions, it induces a term of the form  $\tilde{H}_B = \int \frac{dx}{a^2} [\tilde{B} \tilde{\psi}_{n \uparrow R}^\dagger(x) \tilde{\psi}_{n \downarrow L}(x) + \text{h.c.}]$  (where  $a$  is the short distance cutoff). We assume that  $\tilde{B}$  is large enough such that this term gaps out the small momentum fields  $\tilde{\psi}_{n \uparrow R}$  and  $\tilde{\psi}_{n \downarrow L}$ . We may also write dressed pairing terms of the form  $\tilde{H}_\Delta = \int \frac{dx}{a^2} \left\{ \tilde{\Delta} [\tilde{\psi}_{n \uparrow R}^\dagger(x) \tilde{\psi}_{n \downarrow L}^\dagger(x) + \tilde{\psi}_{n \uparrow L}^\dagger(x) \tilde{\psi}_{n \downarrow R}^\dagger(x)] + \text{h.c.} \right\}$ .

As in the  $\nu = 1$  case, the second term in  $\tilde{H}_\Delta$  involves high-momentum degrees of freedom and does not compete with the Zeeman term,  $\tilde{H}_B$ . It fully gaps out the fields  $\tilde{\psi}_{n \uparrow L}$  and  $\tilde{\psi}_{n \downarrow R}$ . The first term in  $\tilde{H}_\Delta$  competes with the Zeeman field  $\tilde{H}_B$ . For  $\tilde{\Delta} = \tilde{B} = \lambda$ , one obtains

a critical theory, similar to the  $\nu = 1$  case, which in this case is described by a  $\beta^2 = 4\pi m$  self-dual Sine-Gordon model (see Appendix A):

$$H = \int dx \left[ (\partial_x \theta)^2 + (\partial_x \varphi)^2 \right. \\ \left. \frac{\lambda}{a^2} \left\{ \cos(\sqrt{4\pi m} \varphi) + \cos(\sqrt{4\pi m} \theta) \right\} \right], \quad (9)$$

where we have defined  $\varphi = \frac{\eta_{n \uparrow R} - \eta_{n \downarrow L}}{2\sqrt{\pi m}}$  and  $\theta = \frac{\eta_{n \uparrow R} + \eta_{n \downarrow L}}{2\sqrt{\pi m}}$ .

It is, however, a priori unclear whether the critical line  $\tilde{B} = \tilde{\Delta}$  is dominated by the  $\tilde{B}$  and  $\tilde{\Delta}$  terms. In the weak-coupling limit, both  $\tilde{B}$  and  $\tilde{\Delta}$  flow to zero, giving a trivial Luttinger-liquid fixed point. However, it turns out that when  $\tilde{B}$  and  $\tilde{\Delta}$  are equal and large enough, a non-trivial multicritical point is encountered.

To show this, we follow the analysis in Ref. [44], and employ an  $\epsilon$ -expansion, with  $m = 2 + \epsilon$ . In this approach, the scaling dimensions of the  $\tilde{B}$  and  $\tilde{\Delta}$  terms are small, thus pushing the competition between the first and higher order terms of the RG equations to the region in which the perturbative RG analysis applies. As we show in Appendix A, the RG equation describing the flow of  $\lambda = \tilde{B} = \tilde{\Delta}$  takes the form

$$\frac{d\lambda}{dl} = -\epsilon\lambda + \pi^2\lambda^3. \quad (10)$$

When  $\lambda > \sqrt{\epsilon}/\pi$ , a flow to large coupling ensues and the low energy theory is no longer capable of describing the model. The point  $\lambda = \sqrt{\epsilon}/\pi$  is a multicritical point separating the  $\tilde{B}$ -dominated phase, the  $\tilde{\Delta}$ -dominated phase, and the gapless phase. Extrapolating to  $\epsilon$  of order unity, we assume that such a critical point persists. For completeness, we study the full phase diagram of the system in Appendix A.

To uncover the nature of the CFT describing the multicritical point, it is useful to review the physics of classical 2D  $\mathbb{Z}_k$  (clock or Potts) models. As discussed in detail in Refs. [45–47], such models possess self-dual lines. For  $k \leq 4$ , there is a self-dual critical point that separates the disordered and ordered ( $\mathbb{Z}_k$  symmetry broken) phases. For  $k > 4$ , some regions of the self-dual line are contained in gapless phases, while others consist of first order transitions. The different regions of the self-dual line are separated by multicritical points [45, 47]. It was argued in Ref. [36] that these are described by a  $\mathbb{Z}_k$  parafermion CFT. In addition, it is well known that the low energy physics of self-dual  $\mathbb{Z}_k$  models is described by  $\beta^2 = 2\pi k$  self-dual Sine-Gordon models [48, 49]. The above prompts us to identify the finite-coupling multicritical point in our self-dual Sine-Gordon models with those of the  $\mathbb{Z}_k$  models. This indicates that our model at the multicritical point is described by a  $\mathbb{Z}_{2m}$  parafermion CFT.

In what follows, we assume that each wire is tuned to the multicritical point, and is therefore described by a  $\mathbb{Z}_{2m}$  parafermion theory. At this critical point, the fields

$$\begin{aligned}\tilde{\alpha}_n(x) &= e^{i\eta_{n\uparrow R}(x)} + e^{-i\eta_{n\uparrow R}(x)} \\ \tilde{\beta}_n(x) &= -i \left[ e^{i\eta_{n\downarrow L}(x)} - e^{-i\eta_{n\downarrow L}(x)} \right]\end{aligned}\quad (11)$$

commute with the inter-mode Hamiltonian  $\tilde{H}_B + \tilde{H}_\Delta$ . As we demonstrate in Appendix B, the propagators describing this low energy theory take the form  $\langle \tilde{\alpha}_n(z) \tilde{\alpha}_n(z') \rangle \propto (z - z')^{-m}$  and  $\langle \tilde{\beta}_n(\bar{z}) \tilde{\beta}_n(\bar{z}') \rangle \propto (\bar{z} - \bar{z}')^{-m}$ , with  $z = x + i\tau$ . We identify these fields with the  $\psi_m$  and  $\bar{\psi}_m$  primary fields of the  $\mathbb{Z}_{2m}$  theory, which indeed have conformal dimension  $m/2$  [36].

Similar to the non-interacting case [see Eq. (5)], we introduce the inter-wire term

$$\tilde{H}_\perp = i\tilde{t}_\perp \sum_n \int \frac{dx}{a^2} \tilde{\alpha}_n(x) \tilde{\beta}_{n+1}(x). \quad (12)$$

Since the inter-wire Hamiltonian in Eq. (12) has the same form as the self-dual intra-wire Hamiltonian and is composed of fields which commute with the intra-wire coupling terms,  $\tilde{t}_\perp$  flows according to the RG equation (10). Therefore, if  $\tilde{t}_\perp$  is large enough, a flow to large coupling ensues and this Hamiltonian leaves the fields  $\tilde{\beta}_1$  and  $\tilde{\alpha}_N$  gapless. These fields represent the local electron operators on the edges. In fact, a full chiral  $\mathbb{Z}_{2m}$  parafermion CFT is expected to reside on each edge. Using the propagator of the  $\tilde{\alpha}$  and  $\tilde{\beta}$  fields, we find that the electrons' tunneling density of states  $N(\omega)$ , associated with the edge, scales with an anomalous exponent:  $N(\omega) \propto \omega^{m-1}$ .

Similar to the non-interacting case, the strict constraints on the various parameters may be lifted as long as the bulk gap does not close.

*Non-abelian defects and  $4\pi m$ -periodic Josephson effect.*— To study the non-Abelian defects residing at the core of vortices, we examine the configuration presented in Fig. 3a. The FCSC is shaped like an annulus, and the flux threading the annulus is given by an odd multiple of  $h/2e$  [57]. In analogy to the non-interacting

case [50], we expect to find zero modes on the two edges of the system. It will prove useful to cut a thin trench in the annulus. In this case, the flux through the center of the annulus can be chosen to enter in the coupling across the trench, and we can deform our system in such a way that connects it with the configuration studied in Refs. [37–39] (see Fig. 3f).

Given that we are only interested in finding zero energy modes, we have a large amount of freedom in deforming the geometry of the problem while preserving its topology. We first fold the edge “inside-out” leading to the bone-shaped configuration depicted in Fig. 3b. We may then shrink the outermost regions without introducing inter-edge coupling. This leads to the simple 1D geometry presented in Fig. 3c, in which the counter-propagating edge modes  $\tilde{\alpha}_R$  and  $\tilde{\beta}_L$  (defined in the region  $0 < x < l$ ) are connected at  $x = 0, l$ .

The zero-mode properties are solely encoded in the low energy edge theory. We therefore have the additional freedom of changing the Hamiltonian governing the gapped degrees of freedom. One must only ensure that the modes  $\tilde{\alpha}_R$  and  $\tilde{\beta}_L$ , and the other primary fields of the parafermion CFT, remain gapless, while the other microscopic degrees of freedom, such as  $\tilde{\alpha}_L$  and  $\tilde{\beta}_R$ , remain gapped.

An auxiliary model, in which the latter fields are coupled directly, while bulk degrees of freedom are projected out, satisfies this condition. The corresponding Hamiltonian is given by

$$\begin{aligned}H_{\text{auxiliary}} &= i\tilde{t}_a \int_0^l dx \tilde{\beta}_R(x) \tilde{\alpha}_L(x) \\ &= \tilde{t}_a \int_0^l dx \left[ \tilde{\psi}_R(x) \tilde{\psi}_L(x) - \tilde{\psi}_R^\dagger(x) \tilde{\psi}_L(x) + \text{h.c.} \right],\end{aligned}\quad (13)$$

where we have used  $\tilde{\alpha}_\rho = \tilde{\psi}_\rho + \tilde{\psi}_\rho^\dagger$  and  $\tilde{\beta}_\rho = (\tilde{\psi}_\rho - \tilde{\psi}_\rho^\dagger)/i$ .

While it gaps  $\tilde{\alpha}_L$  and  $\tilde{\beta}_R$ , this Hamiltonian leaves the fields  $\tilde{\alpha}_R, \tilde{\beta}_L$  gapless. Notice that strictly speaking,  $\tilde{t}_a$  must be tuned to a multicritical point for the low-energy theory to remain identical. However, since we will soon break the self duality of the problem, this will not be important.

The auxiliary model simplifies our analysis, as it allows us to formulate the problem in terms of the chiral bosonic modes  $\eta_R$  and  $\eta_L$ , such that  $\tilde{\psi}_\rho = e^{i\eta_\rho}$ . Mathematically, the Hamiltonian in Eq. (13) describes two edge modes of a  $\nu = 1/m$  fractional quantum Hall state, coupled by a specific combination of ferromagnetic and superconducting terms.

Next, we include the physical coupling between the edge modes across the trench,

$$\begin{aligned}H_{\text{trench}} &= i\tilde{t}(\varphi) \int_0^l dx \tilde{\alpha}_R(x) \tilde{\beta}_L(x) \\ &= \tilde{t}(\varphi) \int_0^l dx \left[ \tilde{\psi}_R(x) \tilde{\psi}_L(x) + \tilde{\psi}_R^\dagger(x) \tilde{\psi}_L(x) + \text{h.c.} \right],\end{aligned}\quad (14)$$

where  $\varphi = 2\pi \frac{\Phi}{h/2e}$ , and  $\Phi = nh/2e$  is the flux through the center of the annulus. In the gauge in which the flux only enters into  $\tilde{t}(\varphi)$ , we have  $\tilde{t}(\varphi) = \tilde{t}_0 \cos(\frac{\varphi}{2})$ .

Finally, it is necessary to introduce the correct boundary conditions, such that  $\tilde{\alpha}_R \rightarrow \tilde{\beta}_L$  at  $x = 0$  and  $\tilde{\beta}_L \rightarrow \tilde{\alpha}_R$  at  $x = l$  (see Fig. 3c). This can be implemented by extending the model to  $-\infty < x < \infty$ , and strongly coupling  $\alpha_R$  and  $\beta_L$  beyond the ends of the physical system, such that they acquire a large gap in these regions. Within the auxiliary model, formulated in terms of the two  $\eta$  fields, we can do this by introducing strong superconducting terms for  $x < 0$  and  $x > l$ :

$$H_{bc} = \Delta_{bc} \int_{x < 0, x > l} dx \left[ \tilde{\psi}_R(x) \tilde{\psi}_L(x) + \text{h.c.} \right]. \quad (15)$$

The full auxiliary model is depicted in Fig. 3d. Alternatively, note that one can also use a ferromagnetic term. This would not change our conclusions regarding the existence of zero modes.

While the choice of coupling constants  $\tilde{t}_a$  and  $\Delta_{bc}$  seems arbitrary, unphysical zero energy degrees of freedom may appear if these are not properly chosen. In order to avoid these, we first choose the auxiliary coupling constant such that  $\text{sgn}(\tilde{t}_a) = \text{sgn}(\Delta_{bc})$  (otherwise the coefficient of the term  $i\tilde{\beta}_R\tilde{\alpha}_L$  changes sign at  $x = 0, l$ ).

An additional consistency condition is obtained by noting that no physical zero-energy modes should appear in the absence of flux. This leads to the constraint  $\text{sgn}(\Delta_{bc}) = \text{sgn}[\tilde{t}(\varphi = 0)]$ .

To be consistent with these constraints, the coefficients of our auxiliary model must satisfy

$$\text{sgn}(\tilde{t}_a) = \text{sgn}(\Delta_{bc}) = \text{sgn}(\tilde{t}_0). \quad (16)$$

Clearly, the gap does not close as long as the various coupling constants do not change sign. In particular, the presence (or absence) of zero-modes is not affected by varying the various parameters without altering their signs. We may therefore choose  $\tilde{t}_0 = \tilde{t}_a |\cos(\frac{\varphi}{2})|^{-1}$ , in which case the Hamiltonian in the region  $0 < x < l$  takes the form

$$\begin{aligned} H_{\text{trench}} + H_{\text{auxiliary}} = & \\ \tilde{t}_a \int_0^l dx \left\{ \tilde{\psi}_R(x) \tilde{\psi}_L(x) \left[ 1 + \text{sgn} \left( \cos \frac{\varphi}{2} \right) \right] \right. & \\ \left. - \tilde{\psi}_R^\dagger(x) \tilde{\psi}_L(x) \left[ 1 - \text{sgn} \left( \cos \frac{\varphi}{2} \right) \right] + \text{h.c.} \right\} & \quad (17) \end{aligned}$$

While the trench allows us to continuously vary  $\varphi$ , we take the discrete values  $\varphi = 2\pi n$ , where  $n$  counts the number of  $h/2e$  vortices. As Eq. (17) implies, if  $\varphi$  is an even multiple of  $2\pi$ , the Hamiltonian reduces to superconducting terms throughout space, thus preventing the existence of zero energy modes (see Fig. 3e). On the other hand, if  $\varphi$  is an odd multiple of  $2\pi$  it is clear that the superconductor in the region  $0 < x < l$  is replaced by a ferromagnet, and we end up with the S-F-S configuration studied in Refs. [37–39] (see Fig. 3f). Notice that if we had chosen to implement the boundary conditions in Eq. (15) using ferromagnetic terms, we would end up with an F-S-F configuration for odd multiples of  $2\pi$ , and ferromagnetic terms throughout space for even multiple of  $2\pi$ .

Following the results of Refs. [37–39], we conclude that the S-F-S and F-S-F configurations found above give rise to parafermion zero-modes  $\xi_i$ , with  $i = 1, 2$ , located at the interfaces  $x = 0, l$ . These operators satisfy

$$\xi_1 \xi_2 = \xi_2 \xi_1 e^{i\frac{\pi}{m}}, \quad (18)$$

and  $\xi_i^{2m} = 1$ . Eq. (17) implies that the spectrum is  $4\pi$ -periodic as a function of  $\varphi$ .

We note that the interfaces correspond to the circular edges of the original annulus, so that this line of arguments indicates that  $h/2e$  vortices in the FCSC system bind protected parafermionic zero-modes. The parafermion nature of these excitations provides a natural generalization to the case where the bulk contains many vortices, each binding a zero-mode generated by  $\xi_i$  ( $i = 1 \cdots 2M$  is an arbitrary index labeling the zero-modes). The parafermions generally satisfy the algebra

$$\xi_i \xi_j = \xi_j \xi_i e^{i\frac{\pi}{m} \text{sgn}(i-j)}, \quad (19)$$

from which one can infer a ground state degeneracy of  $(2m)^M$  for  $2M$  vortices.

Once our annular system is transformed into the setup presented in Fig. 3f for an odd number of vortices, it is natural to ask whether we can control the relative phase between the two effective superconducting order-parameters and measure the Josephson effect, which was previously shown to be  $4\pi m$ -periodic [38, 39].

Recall that the superconductors shown in Fig. 3f were introduced to impose the boundary conditions, and in particular, do not correspond to the physical superconductor in proximity to our system. Nevertheless, we argue that such an effective Josephson junction can be generated by creating a physical Josephson junction in our system. This is done by considering a physical weak link cutting the physical superconductor at a fixed radial coordinate into two concentric annuli (see Fig. 1b). This allows us to control the relative superconducting phases between the external and the internal parts of our system by connecting the two edges with an external superconducting wire, through which flux is inserted.

Since the edges of our annular system correspond to the interfaces in the auxiliary configuration, we effectively control the relative phases between the two auxiliary superconductors shown in Fig. 3f [58]. Examining the quasi one dimensional regime, in which coupling between the two edge modes of our annular system is induced, the arguments above indicate that the junction shown in Fig. 1b gives rise to a  $4\pi m$ -periodic Josephson effect.

*Conclusion.*— In this work we have demonstrated that a FCSC phase can be stabilized in an array of coupled wires in the presence of Rashba SOC, Zeeman field, superconducting proximity effects, and strong interactions. The resulting phase was found to give rise to a parafermionic edge theory, whose central charge is  $c = \frac{2m-1}{m+1}$ . In this theory, the electron has an anomalous tunneling density of states of the form  $N(\omega) \propto \omega^{m-1}$ . We have additionally found that  $h/2e$  vortices in such a system bind parafermionic zero modes, with quantum dimension  $\sqrt{2m}$ .

Clearly, the FCSC phase we construct is topologically ordered. While we leave the detailed study of the bulk

excitations to future studies, we anticipate that the topologically distinct bulk excitations will be associated with the various low-energy sectors of the parafermionic edge theory through the bulk-edge correspondence. The low energy sectors are generated by the primary fields of the parafermion CFT, which can be labeled by  $\Phi_{[k,\bar{k}]}$  [36], where the integers  $k$  and  $\bar{k}$  are defined mod  $4m$ , and  $k + \bar{k}$  is even. In terms of these, the parafermion fields are given by  $\psi_n = \Phi_{[2n,0]}$  and  $\bar{\psi}_n = \Phi_{[0,2n]}$  (with  $n = 1, \dots, 2m - 1$ ), and the spin operators  $\sigma_n$  are given by  $\sigma_n = \Phi_{[n,n]}$ .

However, in identifying the deconfined bulk excitations with the primary fields of the edge CFT, we must exclude the operators which acquire a non-trivial phase as they wind around the electron, which in our case is identified with the field  $\psi_m$  (or  $\bar{\psi}_m$ ). In particular, since the electron acquires a phase of  $\pi$  as it winds around a vortex, the corresponding field must be associated with a confined excitation (i.e., the energy of two such excitations diverges as we separate them [59]). More generally, the phase associated with winding  $\Phi_{[k,\bar{k}]}$  around the electron  $\psi_m$  ( $\bar{\psi}_m$ ) is given by  $\gamma_{[k,\bar{k}]} = \pi k$  ( $\bar{\gamma}_{[k,\bar{k}]} = \pi \bar{k}$ ) [36]. This shows, for example, that while the parafermion fields  $\psi_n$  are all deconfined in the bulk, the spin operators  $\sigma_n$ , with

odd  $n$ , must be confined.

It has recently been shown that repulsive interactions can stabilize a time reversal invariant topological superconducting (TRITOPS) phase in quantum wires [51–56]. It would be interesting to consider an array of such 1D systems as a possible realization of a fractional TRITOPS in 2D.

- [57] We note that depending on the specific details of the model, the role of even and odd number of vortices may interchange.
- [58] Notice that the phase differences in the effective and the physical Josephson junctions play a similar role in changing the wave function of the low energy electron operators. This indicates that changing the phase difference in the physical junction results in a phase difference in the effective junction as well.
- [59] Notice that such confined excitation can be introduced to the system externally. For example, a vortex in a  $p_x + ip_y$  superfluid is confined, but it can be induced by applying an external effective magnetic field.

## Appendix A: The renormalization group equations of the self-dual Sine-Gordon model

### 1. The $\epsilon$ expansion

The Hamiltonians describing either the inter- and intra- wire coupling terms, discussed in the main text, can be written as

$$H = \int dx \left[ \frac{1}{2\pi m} (\partial_x \eta_1)^2 + \frac{1}{2\pi m} (\partial_x \eta_2)^2 + \frac{\tilde{B}}{a^2} \cos(\eta_1 - \eta_2) + \frac{\tilde{\Delta}}{a^2} \cos(\eta_1 + \eta_2) \right],$$

where  $\eta_1$  ( $\eta_2$ ) is a right (left) moving mode satisfying

$$[\eta_j(x), \eta_j(x')] = m\pi i (-1)^j \text{sign}(x - x'),$$

and the units were chosen such that the Fermi-velocity is  $v = 1$ . Specifically, in the main text, the coefficients were tuned to the self dual line, such that  $\tilde{B} = \tilde{\Delta}$ .

To write the Hamiltonian in a more convenient form, we define

$$\begin{aligned} \varphi &= \frac{\eta_1 - \eta_2}{2\sqrt{\pi m}} \\ \theta &= \frac{\eta_1 + \eta_2}{2\sqrt{\pi m}}. \end{aligned}$$

The commutation relations of these fields are given by

$$[\varphi(x), \theta(x')] = i\Theta(x - x').$$

In terms of these, the Hamiltonian takes the form

$$H = \int dx \left[ (\partial_x \theta)^2 + (\partial_x \varphi)^2 + \frac{\tilde{B}}{a^2} \cos(2\sqrt{\pi m} \varphi) + \frac{\tilde{\Delta}}{a^2} \cos(2\sqrt{\pi m} \theta) \right]$$

We next wish to isolate the explicit cutoff dependence by writing the cosines in terms of their normal-ordered versions:

$$\cos(2\sqrt{\pi m} \varphi) =: \cos(2\sqrt{\pi m} \varphi) : e^{-2m\pi \langle \varphi^2 \rangle}$$

$$\cos(2\sqrt{\pi m} \theta) =: \cos(2\sqrt{\pi m} \theta) : e^{-2m\pi \langle \theta^2 \rangle},$$

where the averages are taken with respect to the quadratic part of the Hamiltonian.

Denoting the small distance cutoff by  $a$  and the large distance cutoff by  $L$ , we find that

$$e^{-2m\pi \langle \varphi^2 \rangle} = e^{-2m\pi \langle \theta^2 \rangle} = \left( \frac{a}{L} \right)^m.$$

Therefore, the Hamiltonian can be written in the form

$$H = \int dx \left[ (\partial_x \theta)^2 + (\partial_x \varphi)^2 + \frac{\tilde{B}}{L^2} \left( \frac{a}{L} \right)^{m-2} : \cos(2\sqrt{\pi m} \varphi) : + \frac{\tilde{\Delta}}{L^2} \left( \frac{a}{L} \right)^{m-2} : \cos(2\sqrt{\pi m} \theta) : \right].$$

In performing the renormalization group, we quantify the dependence of the coefficients on  $l = \log \frac{L}{a}$ .

At tree level, we simply use the explicit cutoff dependence of the coefficients to calculate  $\frac{d\tilde{B}}{dl}$ ,  $\frac{d\tilde{\Delta}}{dl}$ , with  $\tilde{B} = \tilde{B} \left( \frac{a}{L} \right)^{m-2}$ ,  $\tilde{\Delta} = \tilde{\Delta} \left( \frac{a}{L} \right)^{m-2}$ . The resulting tree level RG equations are given by

$$\begin{aligned} \frac{d\tilde{B}}{dl} &= (2 - m) \tilde{B} \\ \frac{d\tilde{\Delta}}{dl} &= (2 - m) \tilde{\Delta}, \end{aligned}$$

giving a flow to weak coupling for  $m > 2$ . This is true in particular at the self-dual point  $\tilde{B} = \tilde{\Delta} = \tilde{\lambda}$  we wish to focus on.

Clearly, if a flow to large coupling is to occur for large  $\lambda$ , it must result from higher order terms. The next possible non-vanishing correction to the RG equation of  $\lambda$  is of order  $\lambda^3$ , as the second order correction vanishes at the self-dual line. Indeed, if the  $\lambda^3$  term has a positive coefficient, it induces a flow to large couplings for large  $\lambda$ . However, for such a term to overcome the negative contribution of the first order term,  $\lambda$  should be of order 1 (assuming the coefficients are of order 1 and recalling that in our model  $m = 3, 5$ , etc.). Such a situation steps beyond the range of validity of the perturbative RG analysis.

To overcome the above technical difficulty, we study the situation in which  $m$  is slightly above its marginal value:  $m = 2 + \epsilon$ , with  $\epsilon \ll 1$ . In this case, the negative first order contribution is proportional to  $\epsilon$ :

$$\begin{aligned} \frac{d\bar{B}}{dl} &= -\epsilon B \\ \frac{d\bar{\Delta}}{dl} &= -\epsilon \Delta, \end{aligned}$$

and therefore, if the third order contribution is positive, the critical point between the two regimes is controlled by the small parameter  $\epsilon$  and is therefore expected to be within the range of validity of the perturbative RG analysis. Indeed, we will find such a critical point satisfying  $\lambda_c \propto \sqrt{\epsilon}$ .

The critical point found for small  $\epsilon$  indicates that a similar critical point exists for  $\epsilon = 1$  as well, above which the coupling constants flows to large coupling (assuming no additional critical points are induced as  $\epsilon$  is increased from  $0 < \epsilon \ll 1$  to  $\epsilon = 1$ ).

We next turn to explicitly derive the form of the third order RG equations. The analysis presented below closely parallels the analysis presented in Ref. [44].

## 2. Third order RG equations and the phase diagram

To calculate the higher orders of the renormalization group equations, we generally write the partition function as

$$Z = \int D\varphi e^{-S_0 - S_1},$$

---

$$-\frac{\bar{B}^2}{2} \int d^2x_1 d^2x_2 L^{-4} : \cos\left(\sqrt{8\pi(1+\delta_B)}\varphi(\vec{x}_1)\right) :: \cos\left(\sqrt{8\pi(1+\delta_B)}\varphi(\vec{x}_2)\right) : . \quad (\text{A3})$$

In order to calculate the OPE [44], we use the definition of normal ordering to write

$$\begin{aligned} &: \cos\left(\sqrt{8\pi(1+\delta_B)}\varphi(\vec{x}_1)\right) :: \cos\left(\sqrt{8\pi(1+\delta_B)}\varphi(\vec{x}_2)\right) : \\ &= e^{8\pi(1+\delta_B)\langle\varphi^2\rangle} \cos\left(\sqrt{8\pi(1+\delta_B)}\varphi(\vec{x}_1)\right) \cos\left(\sqrt{8\pi(1+\delta_B)}\varphi(\vec{x}_2)\right). \end{aligned}$$

This can be rewritten as

$$\frac{1}{2} e^{8\pi(1+\delta_B)\langle\varphi^2\rangle} \left[ \cos\left(\sqrt{8\pi(1+\delta_B)}\{\varphi(\vec{x}_1) + \varphi(\vec{x}_2)\}\right) + \cos\left(\sqrt{8\pi(1+\delta_B)}\{\varphi(\vec{x}_1) - \varphi(\vec{x}_2)\}\right) \right].$$

with

$$S_0 = \frac{1}{2} \int d\tau dx \left[ (\partial_\tau \varphi)^2 + (\partial_x \varphi)^2 \right].$$

$$\begin{aligned} S_1 &= \int \frac{d\tau dx}{L^2} \left[ \bar{B} : \cos\left(\sqrt{8\pi(1+\delta_B)}\varphi\right) : \right. \\ &\quad \left. + \bar{\Delta} : \cos\left(\sqrt{8\pi(1+\delta_\Delta)}\theta\right) : \right], \end{aligned}$$

where  $\theta$  is related to  $\varphi$  according to the condition:

$$i\partial_\mu \varphi = \epsilon^{\mu\nu} \partial_\nu \theta. \quad (\text{A1})$$

In addition, we have defined  $\bar{B} = \tilde{B} \left(\frac{a}{L}\right)^{2\delta_B}$ ,  $\bar{\Delta} = \tilde{\Delta} \left(\frac{a}{L}\right)^{2\delta_\Delta}$ .

In order to follow the strategy outlined above, we assume  $\delta_B$  and  $\delta_\Delta$  are small. As these parameters flow as well, we will write the third order RG equations for  $\bar{B}, \bar{\Delta}, \delta_B, \delta_\Delta$ . Once these are derived, we will focus on the self-dual line defined according to  $\bar{B} = \bar{\Delta} = \bar{\lambda}$  and  $\delta_B = \delta_\Delta = \frac{\epsilon}{2}$ .

To derive the RG equations, we expand the partition function in orders of  $S_1$ :

$$Z = \int D\varphi D\theta e^{-S_0} \left( 1 - S_1 + \frac{1}{2} S_1^2 - \frac{1}{6} S_1^3 + \dots \right). \quad (\text{A2})$$

Next, we will use the Operator Product Expansions (OPEs) of the resulting high orders to get corrections to the original action.

Taking only the first order into account, we get the contribution

$$\begin{aligned} \frac{d\bar{B}}{dl} &= -2\delta_B \bar{B} \\ \frac{d\bar{\Delta}}{dl} &= -2\delta_\Delta \bar{\Delta}. \end{aligned}$$

To second order, terms of the form  $\bar{B}^2$  and  $\bar{\Delta}^2$  renormalize the Kinetic term. Notice that we discard the non-singular term of order  $\bar{B}\bar{\Delta}$ , which results in an irrelevant term.

We first calculate the  $\bar{B}^2$  component of  $S_2 = -\frac{1}{2} S_1^2$ :

Writing the two cosines in terms of their normal ordered versions, we get

$$\frac{1}{2} \left[ : \cos \left( \sqrt{8\pi(1+\delta_B)} \{ \varphi(\vec{x}_1) + \varphi(\vec{x}_2) \} \right) : \frac{1}{c(\vec{x}_1 - \vec{x}_2)} \right. \\ \left. + : \cos \left( \sqrt{8\pi(1+\delta_B)} \{ \varphi(\vec{x}_1) - \varphi(\vec{x}_2) \} \right) : c(\vec{x}_1 - \vec{x}_2) \right]$$

with

$$c(\vec{x}_1 - \vec{x}_2) = e^{8\pi(1+\delta_B)\langle \varphi(\vec{x}_1)\varphi(\vec{x}_2) \rangle} = \left( \frac{|\vec{x}_1 - \vec{x}_2|}{L} \right)^{-4(1+\delta_B)}$$

The first term results in irrelevant terms, and is therefore ignored. The second term is dominated by the region in which the two points  $\vec{x}_1$  and  $\vec{x}_2$  are close to each other. This allows us to approximate

$$\cos \left( \sqrt{8\pi(1+\delta_B)} \{ \varphi(\vec{x}_1) - \varphi(\vec{x}_2) \} \right) \\ \approx 1 - 4\pi(1+\delta_B) (\varphi(\vec{x}_1) - \varphi(\vec{x}_2))^2 \\ = 1 - 4\pi(1+\delta_B) ((\vec{x}_1 - \vec{x}_2) \cdot \nabla \varphi(\vec{x}))^2,$$

where  $\vec{x}$  is the center of mass coordinate. Plugging this back into Eq. (A3), and performing the integral over the relative coordinate  $\vec{x}_1 - \vec{x}_2$ , we get a correction of the form

$$2\pi^2 \log \frac{L}{a} \bar{B}^2 (1+\delta_B) \left[ \frac{1}{2} \int ((\partial_x \varphi)^2 + (\partial_\tau \varphi)^2) d^2x \right].$$

Similarly, the  $\bar{\Delta}^2$  terms gives us (up to a constant)

$$: \cos \left( \sqrt{8\pi(1+\delta_\Delta)} \theta(\vec{x}_1) \right) :: \cos \left( \sqrt{8\pi(1+\delta_\Delta)} \theta(\vec{x}_2) \right) : \\ = -\frac{\pi(1+\delta_\Delta) |\vec{x}_1 - \vec{x}_2|^2}{\left( \frac{|\vec{x}_1 - \vec{x}_2|}{L} \right)^{4(1+\delta_\Delta)}} \left[ (\partial_x \theta(\vec{x}))^2 + (\partial_\tau \theta(\vec{x}))^2 \right]. \quad (\text{A4})$$

Using Eq. (A1) and integrating over the relative coordinate, we obtain the correction

$$-2\pi^2 \log \frac{L}{a} \bar{\Delta}^2 (1+\delta_\Delta) \left[ \frac{1}{2} \int ((\partial_x \varphi)^2 + (\partial_\tau \varphi)^2) d^2x \right].$$

Taken together, the second order corrections are given by

$$S_2 = 2\pi^2 \log \frac{L}{a} \{ \bar{B}^2 (1+\delta_B) - \bar{\Delta}^2 (1+\delta_\Delta) \} \\ \times \left[ \frac{1}{2} \int ((\partial_x \varphi)^2 + (\partial_\tau \varphi)^2) d^2x \right].$$

The second order term clearly renormalizes the kinetic part of the action.

The third order contributions are given by a combination of  $S_3^a = \frac{1}{6} S_1^3$  and  $S_3^b = S_1 S_2$  (the latter contribution

arises when one re-exponentiates the partition function in Eq. A2).

We first look at the  $S_3^a$ -term. The corrections of the type  $\bar{B}^3$  and  $\bar{B}\bar{\Delta}^2$  renormalize the  $B$ -term while terms of the form  $\bar{\Delta}^3$  and  $\bar{\Delta}\bar{B}^2$  renormalize the  $\Delta$ -term. Let us first look at the  $\bar{B}^3$  order term:

$$\frac{1}{6} \bar{B}^3 \int \Pi_{n=1}^3 \left[ \frac{d^2 x_n}{L^2} : \cos \left( \sqrt{8\pi(1+\delta_B)} \varphi(\vec{x}_n) \right) : \right].$$

Using the OPE and dropping the non-singular term, we get the correction [44]

$$\frac{\bar{B}^3}{8L^6} \int d^2 x_1 d^2 x_2 d^2 x_3 \left( \frac{L^2 |\vec{x}_1 - \vec{x}_2|^2}{|\vec{x}_1 - \vec{x}_3|^2 |\vec{x}_2 - \vec{x}_3|^2} \right)^m \\ \times : \cos \left( \sqrt{8\pi(1+\delta_B)} (\varphi(\vec{x}_1) + \varphi(\vec{x}_2) - \varphi(\vec{x}_3)) \right) : .$$

Clearly, the most dominant contributions arise when two coordinates approach each other: either  $\vec{x}_1 \rightarrow \vec{x}_3$ , or  $\vec{x}_2 \rightarrow \vec{x}_3$ . However, these divergences are disconnected and are therefore discarded. Thus, the only singular contribution arises when the three different coordinates approach each other. Taking this into account, we approximate

$$: \cos \left( \sqrt{8\pi(1+\delta_B)} (\varphi(\vec{x}_1) + \varphi(\vec{x}_2) - \varphi(\vec{x}_3)) \right) : \\ \approx : \cos \left( \sqrt{8\pi(1+\delta_B)} \varphi(\vec{x}) \right) :,$$

where  $\vec{x}$  is the center of mass coordinate, and therefore

$$\frac{1}{8L^6} \int d^2 x_1 d^2 x_2 d^2 x_3 \left( \frac{L^2 |\vec{x}_1 - \vec{x}_2|^2}{|\vec{x}_1 - \vec{x}_3|^2 |\vec{x}_2 - \vec{x}_3|^2} \right)^2 \\ \times : \cos \left( \sqrt{8\pi(1+\delta_B)} \varphi(\vec{x}) \right) :$$

Integrating over the relative coordinates, and subtracting disconnected terms, we find the correction [44]

$$\frac{2\pi^2 \bar{B}^3}{L^2} \left[ \log \left( \frac{L}{a} \right) \right]^2 \int d^2 x : \cos \left( \sqrt{8\pi(1+\delta_B)} \varphi(\vec{x}) \right) : .$$

Similar considerations show that the  $\bar{B}\bar{\Delta}^2$  term provides a contribution of the form

$$\frac{\pi^2 \bar{B} \bar{\Delta}^2}{L^2} \left[ \log \left( \frac{L}{a} \right) - 2 \left[ \log \left( \frac{L}{a} \right) \right]^2 \right] \\ \times \int d^2 x : \cos \left( \sqrt{8\pi(1+\delta_B)} \varphi(\vec{x}) \right) : .$$

The remaining contribution is of the form  $S_3^b$ . The contribution to the  $B$ -term is given by

$$2\pi^2 \log \frac{L}{a} \bar{B} \{ \bar{B}^2 (1 + \delta_B) - \bar{\Delta}^2 (1 + \delta_\Delta) \} \\ \times \left[ \frac{1}{2} \int d^2 x_1 d^2 x_2 \mu^2 \left( (\partial_x \varphi(\vec{x}_1))^2 + (\partial_\tau \varphi(\vec{x}_1))^2 \right) : \cos \left( \sqrt{8\pi(1 + \delta_B)} \varphi(\vec{x}_2) \right) : \right].$$

Keeping only the third orders in the various scaling parameters, and using the corresponding OPE, we get

$$-2\pi^2 \left( \log \frac{L}{a} \right)^2 \bar{B} \{ \bar{B}^2 - \bar{\Delta}^2 \} \int d^2 x : \cos \left( \sqrt{8\pi(1 + \delta_B)} (\varphi(\vec{x})) \right) : .$$

Analogous corrections can be derived for the  $\Delta$ -field.

Summing the above corrections, we find that the renormalized action is given by

$$S = S_I + 2\pi^2 \log \frac{L}{a} \{ \bar{B}^2 (1 + \delta_B) - \bar{\Delta}^2 (1 + \delta_\Delta) \} \left[ \frac{1}{2} \int \left( (\partial_x \varphi)^2 + (\partial_\tau \varphi)^2 \right) d^2 x \right] \\ + \frac{\pi^2 \bar{B} \bar{\Delta}^2}{L^2} \log \left( \frac{L}{a} \right) \int d^2 x : \cos \left( \sqrt{8\pi(1 + \delta_B)} \varphi(\vec{x}) \right) : \\ + \frac{\pi^2 \bar{\Delta} \bar{B}^2}{L^2} \log \left( \frac{L}{a} \right) \int d^2 x : \cos \left( \sqrt{8\pi(1 + \delta_\Delta)} \theta(\vec{x}) \right) : .$$

Based on the above, the RG equations for the coefficients of the cosine terms are given by

$$\frac{d\bar{B}}{dl} = -2\delta_B \bar{B} + \pi^2 \bar{B} \bar{\Delta}^2 \\ \frac{d\bar{\Delta}}{dl} = -2\delta_\Delta \bar{\Delta} + \pi^2 \bar{\Delta} \bar{B}^2.$$

The correction to the Kinetic term can be eliminated by rescaling the  $\varphi$  and  $\theta$ -fields. This induces a change in the variables  $\delta_B$ ,  $\delta_\Delta$ , leading to the RG equations:

$$\frac{d\delta_B}{dl} = -2\pi^2(1 + \delta_B) [\bar{B}^2(1 + \delta_B) - \bar{\Delta}^2(1 + \delta_\Delta)] \\ \frac{d\delta_\Delta}{dl} = -2\pi^2(1 + \delta_\Delta) [\bar{\Delta}^2(1 + \delta_\Delta) - \bar{B}^2(1 + \delta_B)].$$

Rescaling  $\bar{B}' = \pi^2 \bar{B}$ ,  $\bar{\Delta}' = \pi^2 \bar{\Delta}$ , we finally write the RG equations

$$\frac{d\bar{B}'}{dl} = -2\delta_B \bar{B}' + \bar{B}' \bar{\Delta}'^2 \\ \frac{d\bar{\Delta}'}{dl} = -2\delta_\Delta \bar{\Delta}' + \bar{\Delta}' \bar{B}'^2$$

$$\frac{d\delta_B}{dl} = -2(1 + \delta_B) [\bar{B}'^2(1 + \delta_B) - \bar{\Delta}'^2(1 + \delta_\Delta)] \\ \frac{d\delta_\Delta}{dl} = -2(1 + \delta_\Delta) [\bar{\Delta}'^2(1 + \delta_\Delta) - \bar{B}'^2(1 + \delta_B)] \quad (\text{A5})$$

Fig. 4 presents the phase diagram resulting from the solution of the RG equations shown in Eq. A5. Specifically, the different colors represent different phases based on the flow equations: The red regions represent a  $\Delta$ -dominated phase, the blue region represents a  $B$ -dominated phase, and the green regions represent a gapless state. Figure 4a (4b) were generated by studying the properties of the RG equations for various initial values of  $\bar{B}'$ ,  $\bar{\Delta}'$  and  $\delta_B = \delta_\Delta = \frac{\epsilon}{2}$ , with  $\epsilon = 0.2$  ( $\epsilon = -0.2$ ).

### 3. Studying the self-dual line

Focusing on the self-dual line  $\bar{B}' = \bar{\Delta}' = \bar{\lambda}$ ,  $\delta_B = \delta_\Delta = \epsilon/2$ , we get a single RG equation

$$\frac{d\bar{\lambda}}{dl} = -\epsilon \bar{\lambda} + \bar{\lambda}^3,$$

accompanied by  $\frac{d\epsilon}{dl} = 0$ .

We immediately find a multicritical point at  $\bar{\lambda} = \sqrt{\epsilon}$ , above which a flow to large  $\bar{\lambda}$  ensues.

This shows that if the coupling constants in the self-dual theory studied in the main text are large enough, the cosine terms flow to large coupling.

As we argued in the main text, if  $\bar{\lambda}$  is tuned to the multicritical point, the low energy field theory is not given by the original Luttinger liquid fixed point, but rather by a parafermion CFT.

### Appendix B: The scaling dimension of the local electron fields

In this section, we demonstrate that the scaling dimension of the local electron fields  $\tilde{\alpha}_{nR}(x)$ ,  $\tilde{\beta}_{nL}(x)$  remains  $m/2$  in the presence of the intra-wire interacting term, which is taken to the critical point  $\tilde{\Delta} = \tilde{B} = \lambda$ :

$$\tilde{H}_\Delta + \tilde{H}_B = \lambda i \int dx \tilde{\beta}_{nR} \tilde{\alpha}_{nL}. \quad (\text{B1})$$

We first note that since  $\tilde{\alpha}_{nR}(x)$  and  $\tilde{\beta}_{nL}(x)$  commute with the above interacting Hamiltonian, they remain right and left moving fields, respectively. To demonstrate this, we write the equations of motion of  $\tilde{\alpha}_{nR}(x)$ :

$$\frac{\partial}{\partial \tau} \tilde{\alpha}_{nR}(x, \tau) = [H, \tilde{\alpha}_{nR}(x, \tau)].$$

FIG. 4: The phase diagrams for (a)  $\epsilon = 0.2$  and (b)  $\epsilon = -0.2$ . The red region corresponds to a  $\Delta$ -dominated phase, the blue region corresponds to a  $B$ -terms phase, and the green regions correspond to gapless states.

The Hamiltonian is composed of the kinetic chiral Luttinger liquid Hamiltonian and the interacting Hamiltonian written in Eq. B1. Since  $\tilde{\alpha}_{nR}(x)$  commutes with the latter, we only need to calculate the commutation with the kinetic part,

$$H_K = \frac{v}{4\pi m} \lim_{\epsilon \rightarrow 0} \int \{\partial\eta_{nR}(x)\} \{\partial\eta_{nR}(x + \epsilon)\},$$

$$\begin{aligned} [H, e^{\pm i\eta_{nR}(x)}] &= \frac{v}{4\pi m} \lim_{\epsilon \rightarrow 0} \int dx' \left[ \{\partial\eta_{nR}(x')\} \{\partial\eta_{nR}(x' + \epsilon)\} e^{\pm i\eta_{nR}(x)} - e^{\pm i\eta_{nR}(x)} \{\partial\eta_{nR}(x')\} \{\partial\eta_{nR}(x' + \epsilon)\} \right] \\ &= e^{\pm i\eta_{nR}(x)} \frac{v}{4\pi m} \lim_{\epsilon \rightarrow 0} \int dx' \left[ e^{\mp i\eta_{nR}(x')} \{\partial\eta_{nR}(x')\} \{\partial\eta_{nR}(x' + \epsilon)\} e^{\pm i\eta_{nR}(x)} - \{\partial\eta_{nR}(x')\} \{\partial\eta_{nR}(x' + \epsilon)\} \right]. \end{aligned}$$

Using the commutation relations

$$[\eta_{nR}(x), \partial\eta_{nR}(x')] = -2\pi i m \delta(x - x')$$

and the Baker-Campbell-Hausdorff formula, we write

$$\begin{aligned} e^{\mp i\eta_{nR}(x')} \{\partial\eta_{nR}(x')\} e^{\pm i\eta_{nR}(x)} \\ &= \partial\eta_{nR}(x') \mp i [\eta_{nR}(x), \partial\eta_{nR}(x')] \\ &= \partial\eta_{nR}(x') \mp 2\pi m \delta(x - x'), \end{aligned}$$

and therefore

$$[H, e^{\pm i\eta_{nR}(x)}] = \mp v e^{\pm i\eta_{nR}(x)} \partial\eta_{nR}(x) = -iv \partial e^{\pm i\eta_{nR}(x)}.$$

This gives us the equation of motion

$$\frac{\partial}{\partial \tau} \tilde{\alpha}_{nR}(x, \tau) = -iv \frac{\partial}{\partial x} \tilde{\alpha}_{nR}(x, \tau).$$

Defining  $z = x + iv\tau$ , we may write the above as

$$\frac{\partial}{\partial \bar{z}} \tilde{\alpha}_{nR}(x, \tau) = 0.$$

where we have used point splitting regularization. Since, by definition,  $\tilde{\alpha}_{nR}(x) = e^{i\eta_{nR}} + e^{-i\eta_{nR}}$ , we calculate the commutation relation with each vertex operator separately:

This shows that  $\tilde{\alpha}_{nR}(z)$  remains a right mover in the presence of the interacting Hamiltonian B1. Similarly,  $\tilde{\beta}_{nL}$  satisfies  $\frac{\partial}{\partial \bar{z}} \tilde{\beta}_{nL}(x, \tau) = 0$ , and is therefore a left mover. We note that the above analysis cannot be repeated for the fields  $\tilde{\alpha}_{nL}$  and  $\tilde{\beta}_{nR}$  which do not commute with the interacting Hamiltonian, and are therefore not chiral.

Using the above result, we now turn to calculate the propagator of the remaining chiral fields and show that all corrections to the  $\lambda = 0$  limit vanish identically. For example, calculating the propagator  $g(z - z') = \langle \tilde{\alpha}_{nR}(z) \tilde{\alpha}_{nR}(z') \rangle$ , and treating the interacting Hamiltonian shown in Eq. B1 perturbatively, we can write the correction to any order  $p$  as

$$\begin{aligned} \delta g_p(z - z') &\propto \\ &(\lambda i)^p \left\langle \tilde{\alpha}_{nR}(z) \tilde{\alpha}_{nR}(z') \prod_{i=1}^p \int d^2 z_i \tilde{\beta}_{nR}(z_i, \bar{z}_i) \tilde{\alpha}_{nL}(z_i, \bar{z}_i) \right\rangle_0. \end{aligned} \quad (\text{B2})$$

Since the expectation value is done with respect to the

Kinetic Hamiltonian, we can treat  $\tilde{\alpha}_{nL}$  as a function  $\bar{z}$  only and  $\tilde{\beta}_{nR}$  as a function of  $z$ . Furthermore, we can use the symmetries of the Kinetic Hamiltonian: First, we know that under rotations,  $z \rightarrow ze^{i\theta}$ ,  $\bar{z} \rightarrow \bar{z}e^{-i\theta}$ , the fields transform as  $\tilde{\alpha}_{nR}(z) \rightarrow \tilde{\alpha}_{nR}(z)e^{-i\theta m/2}$ ,  $\tilde{\alpha}_{nL}(\bar{z}) \rightarrow \tilde{\alpha}_{nL}(\bar{z})e^{i\theta m/2}$  (and the same relations for the  $\beta$ -fields). This leads to the condition

$$\delta g_p [(z - z') e^{i\theta}] = e^{-i\theta m} \delta g_p [z - z'],$$

which is satisfied if  $\delta g_p \propto (z - z')^{-m}$ .

Under scale transformations, given by  $z \rightarrow zd$ ,  $\bar{z} \rightarrow \bar{z}d$ , the fields transform as  $\tilde{\alpha}_{nR}(z) \rightarrow$

$\tilde{\alpha}_{nR}(z)d^{-m/2}$ ,  $\tilde{\alpha}_{nL}(\bar{z}) \rightarrow \tilde{\alpha}_{nL}(\bar{z})d^{-m/2}$  (and similarly for the  $\tilde{\beta}$ -fields). In this case we get the condition  $\delta g_p [(z - z') d] = d^{-m+p(2-m)} \delta g_p [z - z']$ , which is satisfied if  $\delta g_p \propto (z - z')^{-m+p(2-m)}$ . Clearly, we have reached a contradiction, which can only be solved if  $\delta g_p [z - z'] = 0$  for any  $p > 0$ . This shows that all corrections to the propagator calculated in the absence of the interacting term vanish, and the scaling dimension of  $\tilde{\alpha}_{nR}$  and  $\tilde{\beta}_{nL}$  therefore remains  $m/2$ .

We note that as the fields  $\tilde{\beta}_{nR}$  and  $\tilde{\alpha}_{nL}$  are no longer chiral, the full propagator is not a holomorphic (or anti-holomorphic) function, and the entire argument fails, as expected.
