5.1 General

General Methods. Catalyst Pd(PPh₃)₄ was freshly prepared according to literature, starting materials were commercial and used as received. 3,5-Diiodobenzoic acid, DPTS, and chiral alcohol (S)-2,5,8,11-tetraoxatetradecan-13-ol were synthesized and kindly provided by Christian Kaiser. Hexane, heptane, toluene, and THF were distilled prior to use under nitrogen or argon atmosphere over sodium/benzophenone or sodium tetraethylaluminum. Acetonitrile and dichloromethane were distilled prior to use under nitrogen or argon over calcium hydride. Triethylamine and diethylamine were distilled prior to use under nitrogen or argon atmosphere over potassium hydroxide. Benzyl alcohol was stirred under argon atmosphere over CaH₂ powder at rt overnight. The suspension was refluxed for few hours, and then distilled at 150 °C/30 mbar.

Propylene oxide (racemic PO or S-(-)-PO) was stirred under argon atmosphere over CaH₂ powder at rt overnight. The suspension was refluxed for few hours, then distilled at 50 °C, stirred for 1h over NaAlEt₄ and again distilled prior to use.

Microwave-assisted polycondensations were performed in a CEM-Discover monomode microwave reactor having a continuous microwave power delivery system from 0 to 300 W. The reactions were carried out in 10-mL sealed glass vials. The temperature was monitored by an IR sensor on the outer surface of the reaction vessel. All the reactions were performed with 50 W at 50 - 55°C. Column chromatography was carried out with 130-400 mesh silica gel.

Analytic methods.

NMR (¹H and ¹³C, respectively) were recorded on Bruker AB 250 (250.1 and 62.9 MHz for ¹H and ¹³C, respectively), Bruker DPX 300 (300.1 and 75 MHz for ¹H and ¹³C, respectively), Bruker AV400 (400.1 and 100.6 MHz for ¹H and ¹³C, respectively) and AC500 (500 and 126 MHz for ¹H and ¹³C, respectively) spectrometers at 23 ± 2 °C using residual protonated solvent signal as internal standard (¹H: δ(CHCl₃) = 7.24 ppm, δ(DMSO) = 2.49 ppm, and ¹³C (CHCl₃) = 77.0 ppm, δ(DMSO) = 39.7 ppm.

Mass spectrometry was performed on Perkin-Elmer Varian Type MAT 771 and CH6 (EI) or Type CH5DF (FAB) instruments.

GPC measurements in THF as the mobile phase were performed on a Waters 515 HPLC pump-GPC system equipped with a Waters 2487 UV detector (254 nm detection wavelength) at 40 °C using a flow rate of 1 mL/min. The samples were separated through Waters Styragel HR1 or HR3 columns with 5 μm bead sizes, which were calibrated with several narrow

polydispersity polystyrene samples using an internal toluene standard. GPC measurements were performed on an Agilent 1100 series HPLC system equipped with three 300 x 8 mm SDV columns (1,000,000 Å, 100,000 Å, 1000 Å) and one 50 x 8 mm SDV column (100 Å) using both UV (230 nm and 280 nm) and RI detection. The measurements were performed in THF at 30 °C using a flow rate of 1 mL/min. The columns were calibrated with several narrow polydispersity polystyrene samples. The HPLC system consisted of a Knaur Eurosphere 7µm C18, 4·120 mm silica gel column and UV-detection at 254 nm with an eluent flow of 1 mL/min.

**Optical spectroscopy.** UV/visible absorption and emission spectra were recorded in spectroscopic grade solvents, using quartz cuvettes of 1 cm path length on a Cary 50 Spectrophotometer and a Cary Eclipse Fluorescence Spectrophotometer, respectively, both equipped with a Peltier thermostated cell holder (T = 25 ± 0.05 °C). The fluorescence samples were excited at the absorbance maximum wavelength, slit widths were set to 5 nm bandpass for excitation and emission. Fluorescence spectra were corrected for variations in photomultiplier response over wavelength using correction curves generated on the instrument. The corrected fluorescence spectra were normalized by the exact optical density (OD) from the corresponding absorbance spectra. For UV-visible absorption OD(λ_{max}) ≈ 1.0 and for fluorescence measurements OD(λ_{max}) ≈ 0.1 were used. Circular dichroism spectra were recorded on a JASCO 700 spectrometer using quartz cuvettes of 1 cm path length at 20 °C. In some cases circular dichroism spectra recorded as θ in millidegrees, were converted to Δε using the equation Δε = θ/(33982·c·l), where Δε is the difference in the molar absorptivity for oppositely polarized light in M^{-1}cm^{-1}, c is concentration in mol/L, and l is the path length.

**PPO-(3-iodo-5-(TMS-ethynyl)benzoate) 94**

A flame-dried flask was loaded under argon with 3-iodo-5-(TMS-ethynyl)benzoic acid 93 (0.034 g, 0.10 mmol), PPO 81b (0.200 g, 0.02 mmol), DPTS (0.009 g, 0.03 mmol), and 0.2 mL dry CH₂Cl₂. The mixture was cooled to 0 °C and a solution of DIC (0.019 g, 0.12 mmol) in 0.1 mL CH₂Cl₂ was added dropwise. The suspension was stirred for 5 d at rt, filtered, the filtrate concentrated. The residue was suspended in toluene, the generated urea filtered off, and the filtrate concentrated. The crude product was recrystallized from acetone at -20 °C (0.186 g, 90%).
