# Role of $\text{HCO}_3^-$ in regulation of cytoplasmic pH in ciliary epithelial cells

HORST HELBIG, CHRISTOPH KORBMACHER, FRIEDERIKE STUMPF, MIGUEL COCA-PRADOS, AND MICHAEL WIEDERHOLT

*Institut für Klinische Physiologie, Klinikum Steglitz der Freien Universität Berlin, D-1000 Berlin 45, Federal Republic of Germany; and Department of Ophthalmology and Visual Science, Yale University School of Medicine, New Haven, Connecticut 06510*

HELBIG, HORST, CHRISTOPH KORBMACHER, FRIEDERIKE STUMPF, MIGUEL COCA-PRADOS, AND MICHAEL WIEDERHOLT. Role of  $\text{HCO}_3^-$  in regulation of cytoplasmic pH in ciliary epithelial cells. *Am. J. Physiol.* 257 (Cell Physiol. 26): C696–C705, 1989.—Cytoplasmic pH ( $\text{pH}_i$ ) was monitored using the pH-sensitive absorbance of 5(6)carboxy-4',5'-dimethylfluorescein in monolayers of a cell clone derived from bovine pigmented ciliary epithelium (PE) transformed with the simian virus 40. 1) Changing extracellular media from a nominally  $\text{HCO}_3^-$ -free solution to a solution containing 28 mM  $\text{HCO}_3^-$ -5%  $\text{CO}_2$  at constant extracellular pH (7.4) resulted in a delayed alkalization of  $\text{pH}_i$ , which was 4,4'-diisothiocyanostilbene-2,2'-disulfonic acid (DIDS) sensitive and was inhibited in  $\text{Na}^+$ -free medium and in  $\text{Cl}^-$ -depleted cells. 2) DIDS pretreatment acidified  $\text{pH}_i$  in  $\text{HCO}_3^-$ -containing media. 3) Replacing extracellular  $\text{Cl}^-$  resulted in a DIDS-sensitive,  $\text{HCO}_3^-$ -dependent, and  $\text{Na}^+$ -independent alkalization. 4) Replacing extracellular  $\text{Na}^+$  in  $\text{HCO}_3^-$ -containing media led to a partly DIDS-sensitive intracellular acidification. 5) Recovery of  $\text{pH}_i$  after an alkali load (acetate prepulse) had a  $\text{HCO}_3^-$ -dependent and DIDS-sensitive component. 6) Two  $\text{Na}^+$ -dependent components participated in  $\text{pH}_i$  regulation after an acid load ( $\text{NH}_4^+$  prepulse) in  $\text{HCO}_3^-$ -containing solution. One was amiloride sensitive, the other was DIDS sensitive and was inhibited in  $\text{HCO}_3^-$ -free media and after  $\text{Cl}^-$  depletion. We conclude that in cultured PE, in addition to  $\text{Na}^+$ - $\text{H}^+$  exchange, two  $\text{HCO}_3^-$  transporters participate in  $\text{pH}_i$  regulation.  $\text{Cl}^-$ -dependent  $\text{Na}^+$ - $\text{HCO}_3^-$  symport regulates  $\text{pH}_i$  during steady state and after an acid load, and  $\text{Na}^+$ -independent  $\text{Cl}^-$ - $\text{HCO}_3^-$  exchange is involved in  $\text{pH}_i$  recovery after an alkali load.

ciliary epithelium; tissue culture; intracellular pH; chloride-bicarbonate exchange; sodium-bicarbonate cotransport

THE REGULATION of cytoplasmic pH ( $\text{pH}_i$ ) is an essential feature of cell homeostasis. Most biochemical and biophysical processes are sensitive to change in  $\text{pH}_i$ . Production of acid equivalents derived from metabolic activities or  $\text{H}^+$  leaking downhill into the cell must be continuously extruded out of the cell to keep  $\text{pH}_i$  constant. In many cells  $\text{Na}^+$ - $\text{H}^+$  exchange is one of the mechanisms responsible for regulation of  $\text{pH}_i$ . In addition, some cells possess  $\text{HCO}_3^-$ -dependent transport systems that participate in  $\text{pH}_i$  regulation (28).

In some epithelia, transporters for  $\text{HCO}_3^-$  or  $\text{H}^+$  have a dual role. In addition to their function in  $\text{pH}_i$  regulation they are involved in transepithelial transport of acid

equivalents (28),  $\text{Na}^+$ , or  $\text{Cl}^-$  (27). Similar mechanisms may also be present in the ciliary epithelium. This double-layered epithelium, with the pigmented layer (PE) on the stromal side and the nonpigmented layer facing the aqueous humor, is responsible for the formation of aqueous humor and the maintenance of intraocular pressure mainly by active cellular electrolyte secretion (23). Inhibitors of the carbonic anhydrase are widely used clinically to reduce aqueous humor formation rate and thereby lower intraocular pressure (3), although their exact mode of action is unknown. In Ussing-chamber experiments transepithelial current across the ciliary epithelium (21) and transepithelial net  $\text{Cl}^-$  fluxes (20) were found to be  $\text{HCO}_3^-$  dependent. Thus  $\text{HCO}_3^-$  seems to be involved in the basic mechanisms of aqueous humor secretion.

Recently we have shown that in cultured bovine PE  $\text{Na}^+$ - $\text{H}^+$  exchange is responsible for regulation of  $\text{pH}_i$  during steady-state conditions and after an acid load in  $\text{HCO}_3^-$ -free media (14, 16). The aim of the present study was to investigate the role of  $\text{HCO}_3^-$ -transport systems in  $\text{pH}_i$  regulation.  $\text{pH}_i$  was monitored using the pH-sensitive absorbance of 5(6)carboxy-4',5'-dimethylfluorescein (DMCF) in cultured pigmented ciliary epithelial cells transformed with the wild-type simian virus 40 (SV-40). Our data suggest that PE cells possess two  $\text{HCO}_3^-$ -transporting systems (in addition to  $\text{Na}^+$ - $\text{H}^+$  exchange):  $\text{Na}^+$ -independent  $\text{Cl}^-$ - $\text{HCO}_3^-$  exchange and a  $\text{Cl}^-$ -dependent cotransport for  $\text{Na}^+$  and  $\text{HCO}_3^-$ .

## MATERIALS AND METHODS

*Tissue culture.* Experiments were performed on the same cell clone as previously described (16). In brief, bovine ciliary processes were enzymatically disaggregated (trypsin/EDTA, 0.05/0.02%) and the resulting ciliary epithelial cells infected with SV-40. A transformed clone was isolated essentially as previously described for a human cell clone (12). The cell clone retained properties of PE cells (16). Cultures were grown on Nunclon plastic tissue culture flasks (NUNC, Roskilde, Denmark). Cells were maintained in Dulbecco's modified Eagle's medium (DMEM) containing 10% fetal calf serum, 100 U/ml penicillin, and 100  $\mu\text{g}/\text{ml}$  streptomycin in a 5%  $\text{CO}_2$  atmosphere at 37°C. The medium was changed twice a week. Cells were passaged weekly at a

split ratio of 1:2 or 1:3. Experiments were performed with monolayers grown on plastic cover slips in Leighton tubes (Costar, Cambridge, MA) 3–5 days after reaching confluency, between passage numbers 9 and 29.

**Determination of intracellular pH.** A detailed description of the experimental setup has been previously reported (19). In brief, the absorbance of DMCF is pH sensitive at 509 nm, while being nearly pH insensitive at 470 nm. Thus the ratio of absorbance at 509 and 470 nm gives an estimate of pH. For pH<sub>i</sub> experiments a cell-covered cover slip was cut in half. One-half (indicator cells) was incubated for 40–50 min with DMCF diacetate (100 μM). Intracellular esterases cleave the acetate moiety. The resulting DMCF cannot leave the cell and accumulates intracellularly. The second half of the cover slip (control cells) was incubated in an identical solution that contained no dye. Indicator and control cells were placed in a cuvette in which they could be superfused with different solutions. These test solutions were temperature controlled and appropriately gassed. Transmittance was monitored continuously using a dual-beam (control and indicator) dual-wavelength (509 and 470 nm) photometer. Data are presented as the transmittance ratio at 509 and 470 nm corrected for the non-pH<sub>i</sub> related absorbance changes in the control cells. In some experiments the dual-beam photometer was used to investigate the effect of 4,4'-diisothiocyanostilbene-2,2'-disulfonic acid (DIDS) preincubation on pH<sub>i</sub> regulation. In these experiments one-half of the cover slip was incubated for 30–45 min in HCO<sub>3</sub><sup>-</sup>-free Ringer solution containing 1 mM DIDS at 37°C, whereas the other half of the cover slip was incubated without DIDS. Subsequently both halves of the cover slip were loaded with DMCF as described above, and the pH<sub>i</sub> changes in cells with and without DIDS pretreatment were recorded in parallel in the same experiment. At the end of the recording each experiment was individually calibrated, making pH<sub>i</sub> equal to extracellular pH (pH<sub>o</sub>) by using the K<sup>+</sup>-H<sup>+</sup> ionophore nigericin. The results of each calibration step are indicated on the Y-axis of Figs. 1–10.

**Solutions and sources of chemicals.** Standard HCO<sub>3</sub><sup>-</sup> saline solution contained the following ionic concentrations (in mM): 123 NaCl, 28 NaHCO<sub>3</sub>, 4 KCl, 1.7 CaCl<sub>2</sub>, 1 KH<sub>2</sub>PO<sub>4</sub>, 0.9 MgSO<sub>4</sub>, and 5 glucose. HCO<sub>3</sub><sup>-</sup>-containing solutions were gassed with 5% CO<sub>2</sub> resulting in a pH of 7.4. HCO<sub>3</sub><sup>-</sup>-free solutions were buffered with 10 mM *N*-2-hydroxyethylpiperazine-*N'*-2-ethanesulfonic acid (HEPES) to pH 7.4 (if not indicated otherwise) and not gassed. In these solutions 28 mM NaHCO<sub>3</sub> was replaced by 28 mM NaCl. In solutions containing a lower Na<sup>+</sup> or Cl<sup>-</sup> concentration, Na<sup>+</sup> was replaced by *N*-methyl-D-glucamine (NMDG) and Cl<sup>-</sup> by equimolar amounts of cyclamate. In some experiments in Cl<sup>-</sup>-free media, Ca<sup>2+</sup> concentration was raised to 6 mM to compensate for formation of Ca<sup>2+</sup> complexes with large anions. We obtained identical results with solutions containing either 1.7 or 6 mM Ca<sup>2+</sup>, indicating that changes in extracellular Ca<sup>2+</sup> activity were not responsible for the pH<sub>i</sub> changes observed in Cl<sup>-</sup>-free media. In solutions designed to change pH<sub>i</sub> by nonionic diffusion, 20 mM NaCl was replaced by 20 mM NH<sub>4</sub>Cl [or 10 mM (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> in Cl<sup>-</sup>-free media], or 40 mM NaCl by 40 mM sodium acetate

TABLE 1. Intracellular pH at different extracellular pH in HCO<sub>3</sub><sup>-</sup>-free media

Extracellular pH	Intracellular pH	n
7.0	6.89±0.05	8
7.5	7.08±0.03	19
8.0	7.26±0.02	11

Values are means ± SE for pH units; n, no. of experiments.

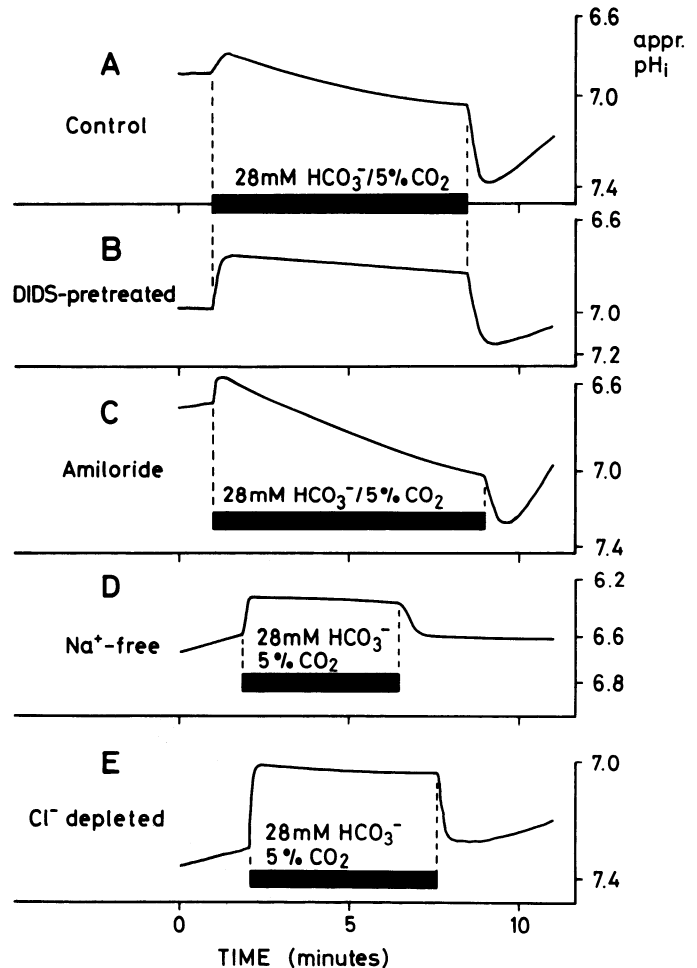

FIG. 1. A: effect of addition of 28 mM HCO<sub>3</sub><sup>-</sup>-5% CO<sub>2</sub> at constant extracellular pH (pH<sub>o</sub>) 7.4 on intracellular pH (pH<sub>i</sub>) under control conditions (12 experiments with similar results). B: same experiments as in A, but cells were preincubated for 35 min at 37°C in HCO<sub>3</sub><sup>-</sup>-free Ringer solution containing 1 mM DIDS, before they were loaded with dye, whereas in A, cells were preincubated without DIDS (4 experiments with similar results). C: effect of amiloride on pH<sub>i</sub> changes induced by addition of HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub>. Before HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub> was added, cells had been superfused for 15 min with a solution containing 1 mM amiloride, until pH<sub>i</sub> approached a new steady-state value (7 experiments with similar results). D: monolayer had been superfused for 10 min with a HCO<sub>3</sub><sup>-</sup> and Na<sup>+</sup>-free saline solution, (9 experiments with similar results). E: effect of addition of HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub> to Cl<sup>-</sup>-depleted cells. Monolayer had been loaded with dye for 50 min in a Cl<sup>-</sup> and HCO<sub>3</sub><sup>-</sup>-free (isosmotically replaced by cyclamate) saline solution (4 experiments with similar results).

or sodium propionate. Osmolality was adjusted with mannitol as required. All tissue culture materials and supplements were obtained from Biochrom KG, Berlin, FRG. DMCF diacetate was purchased from Molecular

FIG. 2. Effect of addition of 40 mM propionate on p*H*<sub>i</sub> in HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub>-containing and HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub>-free ( $\phi$ HCO<sub>3</sub><sup>-</sup>) media (8 experiments with similar results). For calculations of intracellular buffering capacity p*H*<sub>i</sub> change induced by addition of acid in absence of regulatory acid extrusion must be determined. We corrected observed maximum acidification by estimating regulatory acid extrusion from slope of recovery after acid load.

Probes, Eugene, OR. Nigericin, DIDS, 4-acetamido-4'-isothiocyanostilbene-2,2'-disulfonic acid (SITS), and amiloride were purchased from Sigma Chemical, St. Louis, MO.

## RESULTS

**Steady-state p*H*<sub>i</sub>.** In standard HCO<sub>3</sub><sup>-</sup> Ringer solution (28 mM HCO<sub>3</sub><sup>-</sup> gassed with 5% CO<sub>2</sub>, pH 7.4), p*H*<sub>i</sub> in SV-40-transformed bovine PE averaged  $7.13 \pm 0.01$  ( $n = 77$ ). In HCO<sub>3</sub><sup>-</sup>-free solution buffered with 10 mM HEPES to pH 7.4, steady-state p*H*<sub>i</sub> in the same cell clone was  $6.98 \pm 0.01$  ( $n = 57$ ) (16). Thus at constant p*H*<sub>o</sub> the steady-state p*H*<sub>i</sub> was 0.15 pH units more alkaline in a HCO<sub>3</sub><sup>-</sup>-containing solution than in HCO<sub>3</sub><sup>-</sup>-free medium. Steady-state p*H*<sub>i</sub> in HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub> containing media was  $0.09 \pm 0.03$  ( $n = 12$ ) pH units more acidic after DIDS pretreatment than in control cells ( $P < 0.01$ , paired Student's *t* test).

In another set of experiments we tested the effect on p*H*<sub>i</sub> of changing p*H*<sub>o</sub> in HCO<sub>3</sub><sup>-</sup>-free solutions. When p*H*<sub>o</sub> was changed from 7.5 to 7.0 or 8.0, p*H*<sub>i</sub> changed very slowly and reached a new steady-state value within ~10–15 min. Exact values are given in Table 1. p*H*<sub>o</sub> changes of 0.5 pH units result in changes of p*H*<sub>i</sub> of only ~0.2 pH units.

**Changing extracellular HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub> concentration.** To further investigate the difference in steady-state p*H*<sub>i</sub> between HCO<sub>3</sub><sup>-</sup>-containing and HCO<sub>3</sub><sup>-</sup>-free media, experiments such as that shown in Fig. 1 were performed. p*H*<sub>i</sub> was monitored when the superfusing solution was changed from a HCO<sub>3</sub><sup>-</sup>-free HEPES-buffered solution to a solution containing 28 mM HCO<sub>3</sub><sup>-</sup> gassed with 5% CO<sub>2</sub> at a constant p*H*<sub>o</sub> of 7.4. On addition of HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub>, p*H*<sub>i</sub> initially dropped, probably due to nonionic diffusion of CO<sub>2</sub>. Subsequently we observed an alkalization of p*H*<sub>i</sub> toward a new steady-state value, which was  $0.13 \pm 0.01$  ( $n = 2$ ) pH units more alkaline than the steady-state p*H*<sub>i</sub>

in HCO<sub>3</sub><sup>-</sup>-free solution. If HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub> was removed inverted p*H*<sub>i</sub> changes occurred. Because the Cl<sup>-</sup> concentration in HCO<sub>3</sub><sup>-</sup>-free media was 28 mM higher than in HCO<sub>3</sub><sup>-</sup>-containing solutions, we performed experiments such as that shown in Fig. 1A, in which 28 mM cyclamate replaced HCO<sub>3</sub><sup>-</sup>. We observed identical results as shown in Fig. 1A ( $n = 4$ ).

In DIDS-pretreated cells ( $n = 4$ , Fig. 1B) we observed the initial acidification after addition of HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub>. The subsequent alkalization was nearly totally blocked. In the presence of 1 mM amiloride the p*H*<sub>i</sub> changes on addition of HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub> were similar to the changes in control experiments, but the difference in steady-state p*H*<sub>i</sub> was increased ( $0.33 \pm 0.04$  pH units;  $n = 7$ ; Fig. 1C). However, in Na<sup>+</sup>-free media ( $n = 9$ ; Fig. 1D) only the initial (probably CO<sub>2</sub> related) fall in p*H*<sub>i</sub> was observed. The subsequent alkalization was markedly reduced. A similar inhibition of the delayed alkalization was observed if the experiment was performed in Cl<sup>-</sup>-free medium with Cl<sup>-</sup>-depleted cells (incubation with the dye for 50 min in Cl<sup>-</sup> and HCO<sub>3</sub><sup>-</sup>-free medium;  $n = 4$ ; Fig. 1E).

**Intracellular buffering capacity.** Intracellular buffering capacity was evaluated using the weak acid propionic acid. Addition of 40 mM propionic acid to the superfusing solution resulted in a sharp fall in p*H*<sub>i</sub> due to nonionic diffusion of uncharged propionic acid and intracellular cleavage into H<sup>+</sup> and anionic propionate. In the experiment shown in Fig. 2, 40 mM propionic acid was added for a brief period in HCO<sub>3</sub><sup>-</sup>-free and HCO<sub>3</sub><sup>-</sup>-containing media. It is obvious that in HCO<sub>3</sub><sup>-</sup>-free solution propionic acid resulted in a much larger p*H*<sub>i</sub> change ( $-0.45 \pm 0.02$  pH units;  $n = 8$ ) than in HCO<sub>3</sub><sup>-</sup> Ringer solution ( $-0.25 \pm 0.02$  pH units;  $n = 8$ ). From the amplitude of the p*H*<sub>i</sub> changes, the intracellular buffering capacity ( $\beta$ ) can be estimated<sup>1</sup>. The data revealed values of 35.6 mM H<sup>+</sup>/pH

<sup>1</sup>  $\beta = \Delta[(\text{CH}_3)_2\text{COO}^-]_i \cdot (\Delta\text{pH}_i)^{-1}$ ; see Ref. 28.

TABLE 2. Effect of Cl<sup>-</sup> replacement by cyclamate on pH<sub>i</sub>

Modified Ringer Solution	Initial Rate of Alkalinization on Cl <sup>-</sup> Replacement	n
28 mM HCO <sub>3</sub> <sup>-</sup> gassed with 5% CO <sub>2</sub>		
Control	0.18±0.02	12
DIDS preincubated	0.01±0.01	3
DIDS acute	0.01±0.01	3
Na <sup>+</sup> free	0.11±0.02	7
HCO <sub>3</sub> <sup>-</sup> -CO <sub>2</sub> -free media	0.01±0.01	3

Values are means ± SE for pH units/min; n, no. of experiments.

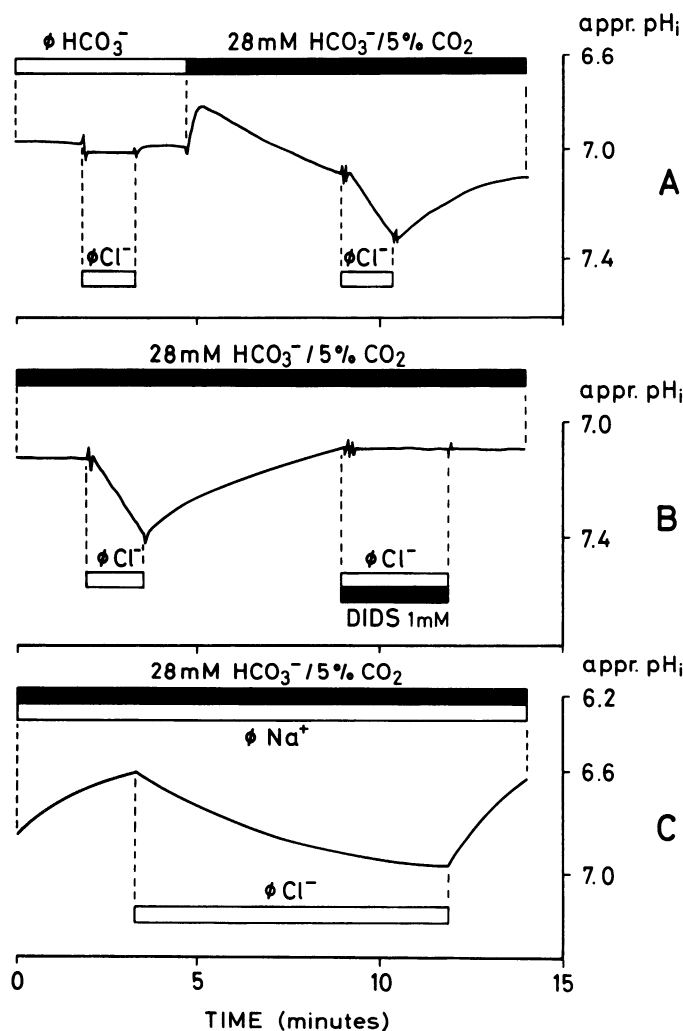

FIG. 3. A: original recording illustrating effect of Cl<sup>-</sup> replacement by cyclamate on cytoplasmic pH in HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub>-containing and HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub>-free (φHCO<sub>3</sub><sup>-</sup>) media (3 experiments with similar results). B: effect of Cl<sup>-</sup> replacement on pH<sub>i</sub> in absence and in presence of 1 mM DIDS (3 experiments with similar results). C: effect of Cl<sup>-</sup> replacement by cyclamate on pH<sub>i</sub> in Na<sup>+</sup>-free (φNa<sup>+</sup>) media [Na<sup>+</sup> isosmotically replaced by *N*-methyl-D-glucamine (NMDG)]. Cells had been superfused for 10 min with Na<sup>+</sup>-free medium before extracellular Cl<sup>-</sup> was removed (7 experiments with similar results). φCl<sup>-</sup>, Cl<sup>-</sup> free.

unit for β in HCO<sub>3</sub><sup>-</sup>-containing media and 12.5 mM H<sup>+</sup>/pH unit for β in HCO<sub>3</sub><sup>-</sup>-free solutions.

**Removing extracellular chloride.** A summary of the effects on pH<sub>i</sub> of replacing extracellular Cl<sup>-</sup> is given in Table 2. The effect on pH<sub>i</sub> of removing extracellular Cl<sup>-</sup>

(by isosmotic replacement with cyclamate) was HCO<sub>3</sub><sup>-</sup> dependent. In HCO<sub>3</sub><sup>-</sup>-free media no significant change in pH<sub>i</sub> was observed on Cl<sup>-</sup> replacement (*n* = 3; Fig. 3A). On the other hand, in HCO<sub>3</sub><sup>-</sup> Ringer solution pH<sub>i</sub> increased by 0.18 ± 0.02 pH units/min (*n* = 12, Fig. 3A) on Cl<sup>-</sup> removal. In the presence of 1 mM DIDS this response was blocked (*n* = 3; Fig. 3B). To test for the Na<sup>+</sup> dependence of this pH<sub>i</sub> response, cells were Na<sup>+</sup> depleted until a new (more acidic) steady-state pH<sub>i</sub> was reached. Subsequently, Cl<sup>-</sup> was replaced in a Na<sup>+</sup>-free HCO<sub>3</sub><sup>-</sup>-containing solution (Fig. 3C). This maneuver resulted in an increase of pH<sub>i</sub> (0.11 ± 0.02 pH units/min; *n* = 7), which was significantly slower than in Na<sup>+</sup>-containing media (*P* < 0.05, unpaired Student's *t* test).

To evaluate the kinetic parameters of the effect of Cl<sup>-</sup> on pH<sub>i</sub>, experiments such as that shown in Fig. 4 were performed. Cells were Cl<sup>-</sup> depleted in a HCO<sub>3</sub><sup>-</sup>-containing solution for 10 min. Subsequently different concentrations of Cl<sup>-</sup> were added. The initial rate of acidification on addition of Cl<sup>-</sup> exhibited saturation with increasing Cl<sup>-</sup> concentration (Fig. 5A). Linear transformation of the data according to Lineweaver-Burk (Fig. 5B) revealed an apparent *K<sub>m</sub>* of 55 mM and a *V<sub>max</sub>* of -0.23 pH units/min.

**Removing extracellular Na<sup>+</sup>.** Table 3 summarizes the effect of Na<sup>+</sup> removal on intracellular pH. Na<sup>+</sup> replacement in HCO<sub>3</sub><sup>-</sup> Ringer solution decreased pH<sub>i</sub> (-0.08 ± 0.01 pH units/min, *n* = 12) and addition of 1 mM amiloride during steady state in HCO<sub>3</sub><sup>-</sup>-containing media did not significantly change pH<sub>i</sub> (*n* = 12; Fig. 6A). Although amiloride (1 mM) slightly inhibited the acidification induced by removing external Na<sup>+</sup> in HCO<sub>3</sub><sup>-</sup> Ringer solution, there was still significant acidification (-0.06 ± 0.02 pH units/min; *n* = 5; Fig. 6A). On the other hand in the presence of 1 mM DIDS the acidification induced by replacing external Na<sup>+</sup> was markedly reduced (-0.04 ± 0.01 pH units/min; *n* = 7; Table 3). Different results were obtained in nominally HCO<sub>3</sub><sup>-</sup>-free solutions. Replacing extracellular Na<sup>+</sup> by NMDG in HCO<sub>3</sub><sup>-</sup>-free media acidified pH<sub>i</sub> by -0.10 ± 0.01 pH units/min (*n* = 25; Fig. 6B). Addition of amiloride (1 mM) to HCO<sub>3</sub><sup>-</sup>-free media resulted in a slight acidification (-0.03 ± 0.01 pH units/min; *n* = 9; Fig. 6B). When Na<sup>+</sup> was removed in the presence of amiloride, there was no significant additive acidification on Na<sup>+</sup> removal in HCO<sub>3</sub><sup>-</sup>-free media (-0.04 ± 0.01 pH units/min; *n* = 13; Fig. 6B).

**Regulation of pH<sub>i</sub> after an alkali load.** An alkali load was imposed using the acetate prepulse technique. Cells were incubated for 10 min in Ringer solution containing 40 mM acetate. Subsequently acetate was removed. pH<sub>i</sub> increased because of the exit of uncharged acetic acid by nonionic diffusion followed by a recovery of pH<sub>i</sub> toward a normal steady-state value. The initial recovery rates after acetate prepulse under different conditions are summarized in Table 4. In HCO<sub>3</sub><sup>-</sup>-containing Ringer solution the recovery rate after acetate prepulse averaged -0.08 ± 0.01 pH units/min (*n* = 9) whereas in HCO<sub>3</sub><sup>-</sup>-free solution the rate of recovery was only -0.05 ± 0.01 pH units/min (*n* = 11). After preincubation with 1 mM DIDS the recovery was markedly reduced in HCO<sub>3</sub><sup>-</sup>

FIG. 4. After dye loading in standard (Cl<sup>-</sup>-containing) solution cells were superfused for 10 min with Cl<sup>-</sup>-free HCO<sub>3</sub><sup>-</sup>-containing media, which led to an alkalinization of p*H*<sub>i</sub>. Subsequently, different Cl<sup>-</sup> concentrations were added for a brief time period (5 experiments with similar results).  $\phi$ , Cl<sup>-</sup> free.

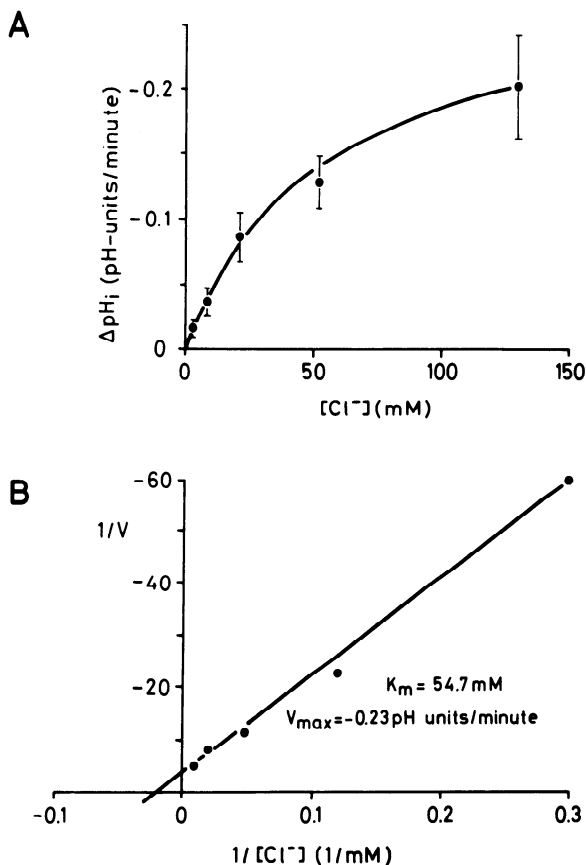

FIG. 5. A: data from 5 experiments such as that shown in Fig. 4 (means  $\pm$  SE) were plotted as rate of acidification of p*H*<sub>i</sub> induced by addition of Cl<sup>-</sup> vs. respective Cl<sup>-</sup> concentration. No attempt was made to compensate for changes in base line, which occurred before and after addition of some of test solutions (see Fig. 4). Therefore rate of change in pH should be interpreted with caution. B: linear transformation of data from A according to Lineweaver-Burk. Regression line (least square method) reveals an apparent  $K_m$  of 54.7 mM, a  $V_{max}$  of -0.23 pH units/min, and  $r^2$  of 0.99.

Ringer ( $-0.02 \pm 0.02$  pH units/min;  $n = 7$ ; Fig. 7). Recovery after an alkali load induced by addition of NH<sub>4</sub><sup>+</sup> was also partly inhibited after DIDS preincubation (data not shown). In HCO<sub>3</sub><sup>-</sup>-free solution replacement of

TABLE 3. Effect of Na<sup>+</sup> replacement and amiloride on p*H*<sub>i</sub>

Modified Ringer Solution	Initial Rate of p <i>H</i> <sub>i</sub> Change	<i>n</i>
28 mM HCO <sub>3</sub> <sup>-</sup> gassed with 5% CO <sub>2</sub>		
Na <sup>+</sup> replacement	$-0.08 \pm 0.01$	12
1 mM amiloride	$-0.004 \pm 0.003$	12
Na <sup>+</sup> replacement + 1 mM amiloride	$-0.06 \pm 0.02$	5
Na <sup>+</sup> replacement + 1 mM DIDS	$-0.04 \pm 0.01$	7
HCO <sub>3</sub> <sup>-</sup> -CO <sub>2</sub> -free media		
Na <sup>+</sup> replacement	$-0.10 \pm 0.01$	25
1 mM amiloride	$-0.03 \pm 0.01$	9
Na <sup>+</sup> replacement + 1 mM amiloride	$-0.04 \pm 0.01$	13

Values are means  $\pm$  SE in pH units/min. *n*, no. of experiments.

Cl<sup>-</sup> had no significant effect on recovery after acetate prepulse ( $-0.05 \pm 0.01$  pH units/min;  $n = 4$ ), whereas in HCO<sub>3</sub><sup>-</sup>-containing solution removing Cl<sup>-</sup> during this recovery reversed p*H*<sub>i</sub> recovery ( $0.14 \pm 0.03$  pH units/min;  $n = 5$ ).

**Regulation of p*H*<sub>i</sub> after an acid load.** Intracellular acid loading was achieved by the NH<sub>4</sub><sup>+</sup> prepulse technique (8). Recovery of p*H*<sub>i</sub> was almost linear during the first few minutes. Initial recovery rates after NH<sub>4</sub><sup>+</sup> prepulse (after incubation for 3–5 min with 20 mM NH<sub>4</sub><sup>+</sup>) are summarized in Table 5. Recovery in HCO<sub>3</sub><sup>-</sup>-free and HCO<sub>3</sub><sup>-</sup>-containing media is shown in Fig. 8. Initial p*H*<sub>i</sub> recovery rate after NH<sub>4</sub><sup>+</sup> prepulse was  $0.15 \pm 0.02$  pH units/min ( $n = 17$ ) in HCO<sub>3</sub><sup>-</sup>-free solution and  $0.19 \pm 0.02$  pH units/min ( $n = 22$ ) in HCO<sub>3</sub><sup>-</sup>-containing Ringer solution. Addition of 1 mM amiloride almost completely abolished p*H*<sub>i</sub> recovery in HCO<sub>3</sub><sup>-</sup>-free solution, whereas in HCO<sub>3</sub><sup>-</sup>-containing Ringer solution only ~50% of p*H*<sub>i</sub> recovery was inhibited by addition of 1 mM amiloride (Fig. 8). Recovery was Na<sup>+</sup> dependent in HCO<sub>3</sub><sup>-</sup>-containing as well as in HCO<sub>3</sub><sup>-</sup>-free solutions. Under both conditions Na<sup>+</sup> replacement reversed recovery.

Acute addition of 1 mM DIDS ( $n = 6$ ) or SITS ( $n = 6$ ) during p*H*<sub>i</sub> recovery after an acid load inhibited up to 50% of the recovery rate in HCO<sub>3</sub><sup>-</sup> Ringer solution (Fig. 9). In HCO<sub>3</sub><sup>-</sup>-free media no significant effect of 1 mM DIDS on p*H*<sub>i</sub> regulation after NH<sub>4</sub><sup>+</sup> prepulse was observed

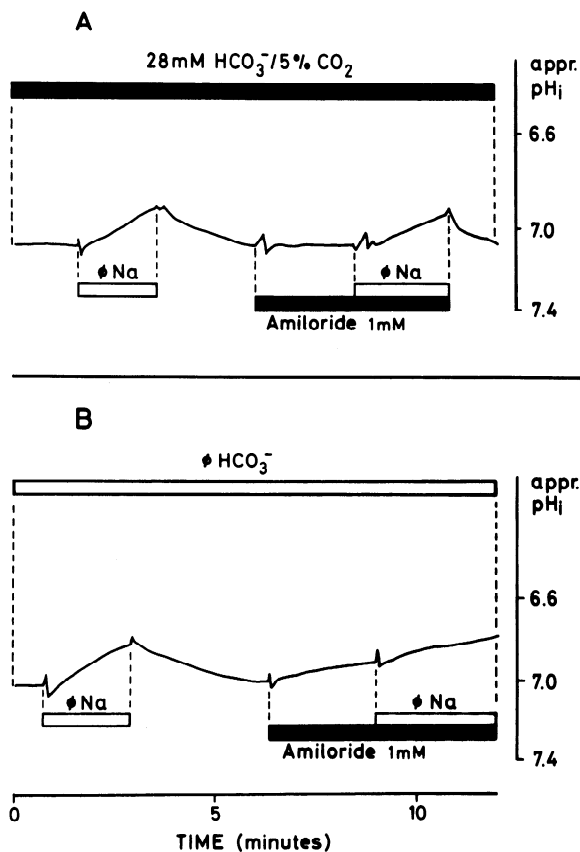

FIG. 6. Effect of Na<sup>+</sup> replacement by NMDG in absence and presence of 1 mM amiloride in HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub>-containing solution (5 experiments with similar results) (A) and in HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub> free ( $\phi$ HCO<sub>3</sub><sup>-</sup>) media (B) (4 experiments with similar results).  $\phi$ Na<sup>+</sup>, Na<sup>+</sup> free.

( $n = 6$ ). Cells pretreated for 30 min (or longer) with 1 mM DIDS also showed a slower pH<sub>i</sub> recovery than control cells (DIDS pretreated:  $0.08 \pm 0.02$  pH units/min;  $n = 5$ ). Addition of 1 mM amiloride to DIDS-pretreated cells almost completely abolished residual pH<sub>i</sub> recovery ( $0.02 \pm 0.003$ ,  $n = 5$ ). In Cl<sup>-</sup>-depleted cells (15 min in Cl<sup>-</sup>-free HCO<sub>3</sub><sup>-</sup>-containing solution) pH<sub>i</sub> recovery after

TABLE 4. Recovery rate of pH<sub>i</sub> after acetate prepulse

Modified Ringer Solution	Initial Rate of pH <sub>i</sub> Recovery	$n$
28 mM HCO <sub>3</sub> <sup>-</sup> gassed with 5% CO <sub>2</sub>		
Control	$-0.08 \pm 0.01$	9
DIDS preincubated	$-0.02 \pm 0.02$	7
Cl <sup>-</sup> free	$+0.14 \pm 0.03$	5
HCO <sub>3</sub> <sup>-</sup> -CO <sub>2</sub> -free media		
Control	$-0.05 \pm 0.01$	11
Cl <sup>-</sup> free	$-0.05 \pm 0.01$	4

NH<sub>4</sub><sup>+</sup> prepulse was  $0.06 \pm 0.01$  pH units/min ( $n = 6$ ; Fig. 10) in HCO<sub>3</sub><sup>-</sup> Ringer solution. This recovery was almost completely abolished by addition of 1 mM amiloride ( $n = 6$ ; Fig. 10).

## DISCUSSION

In this study we have observed marked differences in the regulation of pH<sub>i</sub> in the presence and absence of HCO<sub>3</sub><sup>-</sup>. These differences can be explained by two HCO<sub>3</sub><sup>-</sup>-transporting systems operating in cultured PE: a Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange and a Cl<sup>-</sup>-dependent Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> cotransport. Before the evidence for these transporters is discussed, it should be pointed out that  $\beta$  has to be taken into account if transport of acid equivalents is measured as change in pH<sub>i</sub>. We calculated a  $\beta$  of 12.5 mM H<sup>+</sup>/pH unit for cultured PE in HCO<sub>3</sub><sup>-</sup>-free media (intrinsic buffering capacity,  $\beta_i$ ). This value is rather low compared with other animal cells (28). However, most cultured cells seem to have a relatively low  $\beta_i$  (19). In HCO<sub>3</sub><sup>-</sup>-containing media,  $\beta$  in PE was 35.6 mM H<sup>+</sup>/pH unit. This value is in reasonable agreement with the theoretically calculated additional buffering power for the CO<sub>2</sub>-HCO<sub>3</sub><sup>-</sup> system ( $\beta_{CO_2}$ ) of  $\sim 25$  mM H<sup>+</sup>/pH unit at pH<sub>i</sub> 7.0 and 5% CO<sub>2</sub> (28). Thus, in HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub>-containing media,  $\beta$  is more than twice as large as  $\beta_i$ . The same pH<sub>i</sub> change therefore represents more than twice the rate of H<sup>+</sup> (or OH<sup>-</sup> or HCO<sub>3</sub><sup>-</sup>) transport in HCO<sub>3</sub><sup>-</sup> Ringer solution

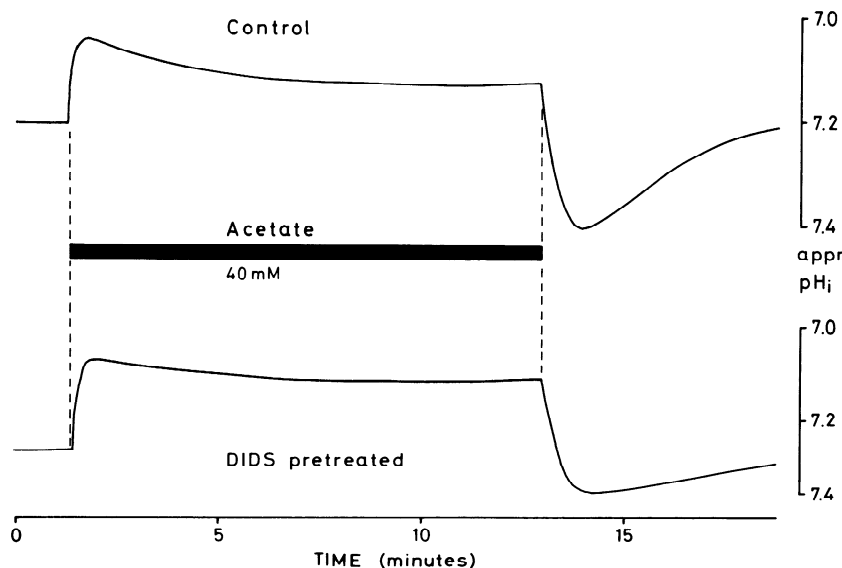

FIG. 7. Cells from same cover slip were incubated in HCO<sub>3</sub><sup>-</sup>-free media at 37°C for 45 min either in absence (control) or in presence of 1 mM DIDS (DIDS pretreated). Subsequently both monolayers were dye loaded. Cells were superfused for 10 min with acetate (40 mM). Removal of acetate led to an alkalization of pH<sub>i</sub> followed by a pH<sub>i</sub> recovery toward normal steady-state pH<sub>i</sub>, which was markedly slower in DIDS-pretreated cells (5 experiments with similar results).

compared with HCO<sub>3</sub><sup>-</sup>-free medium. However, the values for  $\beta$  are only valid for the pH<sub>i</sub> range at which they were obtained.  $\beta_{\text{CO}_2}$  strongly depends on pH<sub>i</sub>, and  $\beta_i$  may also vary considerably at different pH<sub>i</sub> values (28). Thus measurements of pH<sub>i</sub> changes allow only an approximate estimation for transport of acid and base equivalents.

**Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange.** Replacement of extracellular Cl<sup>-</sup> by cyclamate resulted in a HCO<sub>3</sub><sup>-</sup>-dependent and DIDS-sensitive alkalization of pH<sub>i</sub> (Table 2; Fig. 3) that can be explained by an anion transporter exchanging extracellular HCO<sub>3</sub><sup>-</sup> for intracellular Cl<sup>-</sup>. Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange has been described in a variety of different cell types (24) including PE cells by means of <sup>36</sup>Cl-uptake studies (15). Two types of Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchangers have been described: sodium-dependent and sodium-independent anion exchange (22, 23, 25, 32). We therefore tested the alkalization induced by Cl<sup>-</sup> replacement for Na<sup>+</sup> dependence. We still found significant alkalization, when Cl<sup>-</sup> was replaced in Na<sup>+</sup>-free medium (Fig. 3C). However, the rate of pH<sub>i</sub> change on Cl<sup>-</sup> replacement was reduced in

Na<sup>+</sup>-free solution. This reduction cannot be taken as evidence for Na<sup>+</sup> dependence of part of the alkalization induced by Cl<sup>-</sup> removal. Anion exchange has been shown to be pH<sub>i</sub> dependent: intracellular acidification inhibited and intracellular alkalization stimulated anion exchange (26). pH<sub>i</sub> in Na<sup>+</sup>-free solution was more acidic, which could explain the reduced effect of Cl<sup>-</sup> removal on pH<sub>i</sub> in Na<sup>+</sup>-free solutions. Nevertheless we have presented evidence that at least part of Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange is Na<sup>+</sup> independent.

Recovery of pH<sub>i</sub> after an alkali load in PE cells was reversed by replacement of Cl<sup>-</sup> and was partly DIDS sensitive (Fig. 7). If corrected for the different intracellular buffering capacities, the alkali extrusion rate was markedly faster in HCO<sub>3</sub><sup>-</sup>-containing compared with HCO<sub>3</sub><sup>-</sup>-free media (Table 4). These results are similar to those in Vero cells (32) and indicate involvement of Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange in recovery after an alkali load. Participation of anion exchange in regulatory pH<sub>i</sub> decrease is not a general finding (28). In PE cells Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange seems to be involved but is not the only mechanism for recovery after alkali load. There seem to be additional mechanisms, because significant recovery was observed in HCO<sub>3</sub><sup>-</sup>-free medium. Involvement of Cl<sup>-</sup>-OH<sup>-</sup> exchange was excluded, since Cl<sup>-</sup> replacement had no effect on regulatory pH<sub>i</sub> increase in HCO<sub>3</sub><sup>-</sup>-free solutions (Table 4). Passive ionic conductances (H<sup>+</sup>, OH<sup>-</sup>) or accumulation of metabolic acid equivalents may account for the pH<sub>i</sub> regulation observed in HCO<sub>3</sub><sup>-</sup>-free media (28).

We also tried to evaluate kinetic parameters for the effect of Cl<sup>-</sup> on pH<sub>i</sub>. Different concentrations of Cl<sup>-</sup> were added to Cl<sup>-</sup>-depleted cells, and the rate of acidification induced by Cl<sup>-</sup> readdition was plotted against Cl<sup>-</sup> concentration (Figs. 4, 5A). Kinetic analysis revealed an apparent  $K_m$  of 55 mM for Cl<sup>-</sup> (Fig. 5B). Experiments

TABLE 5. Recovery of pH<sub>i</sub> after NH<sub>4</sub><sup>+</sup> prepulse

Modified Ringer Solution	Initial Rate of pH <sub>i</sub> Recovery	n
28 mM HCO <sub>3</sub> <sup>-</sup> gassed with 5% CO <sub>2</sub>		
Control	0.19±0.02	22
1 mM amiloride	0.10±0.01	19
DIDS preincubated	0.08±0.02	5
DIDS preincubated + 1 mM amiloride	0.02±0.003	5
Cl <sup>-</sup> depleted	0.06±0.01	6
Cl <sup>-</sup> depleted + 1 mM amiloride	0.01±0.004	6
Na <sup>+</sup> free	-0.02±0.01	3
HCO <sub>3</sub> <sup>-</sup> -CO <sub>2</sub> -free media		
Control	0.15±0.02	17
1 mM amiloride	0.02±0.01	14
Na <sup>+</sup> free	-0.03±0.02	8

Values are means ± SE for pH units/min; n, no. of experiments.

FIG. 8. Effect of amiloride (1 mM) on pH<sub>i</sub> recovery after acid load induced by NH<sub>4</sub><sup>+</sup> prepulse in presence and in absence ( $\phi\text{HCO}_3^-$ ) of extracellular HCO<sub>3</sub><sup>-</sup> (5 experiments with similar results).

FIG. 9. Effect of DIDS and SITS (1 mM) on p<sub>H<sub>i</sub></sub> recovery after intracellular acid loading induced by NH<sub>4</sub><sup>+</sup> prepulse in presence of extracellular HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub> (5 experiments with similar results).

were performed in the presence of 28 mM extracellular HCO<sub>3</sub><sup>-</sup>. Extracellular HCO<sub>3</sub><sup>-</sup> is known to compete with Cl<sup>-</sup> for a common extracellular binding site. In <sup>36</sup>Cl<sup>-</sup> uptake studies we found a K<sub>m</sub> for Cl<sup>-</sup> of 8 mM in HCO<sub>3</sub><sup>-</sup>-free medium (15). From these data we can estimate the affinity of HCO<sub>3</sub><sup>-</sup> for the extracellular binding site of the anion exchanger<sup>2</sup>. Thus the K<sub>i</sub> for extracellular HCO<sub>3</sub><sup>-</sup> in PE cells is ~5 mM, in good agreement with affinities found in other epithelia (26).

**Na<sup>+</sup>-coupled HCO<sub>3</sub><sup>-</sup> transport.** Recovery of p<sub>H<sub>i</sub></sub> after an acid load (NH<sub>4</sub><sup>+</sup> preload) was almost totally blocked by 1 mM amiloride in the absence of HCO<sub>3</sub><sup>-</sup> (Fig. 8). Thus, in HCO<sub>3</sub><sup>-</sup>-free solutions, amiloride-sensitive Na<sup>+</sup>-H<sup>+</sup> exchange seemed to be the main mechanism responsible for p<sub>H<sub>i</sub></sub> regulation after an acid load (16). In HCO<sub>3</sub><sup>-</sup> Ringer solution (after correction for the higher buffering capacity in HCO<sub>3</sub><sup>-</sup> Ringer) a marked increase in acid extrusion (or alkali accumulation) rate was observed (Table 5). In HCO<sub>3</sub><sup>-</sup> Ringer solution we found a second mechanism involved in p<sub>H<sub>i</sub></sub> recovery after an acid load, being DIDS sensitive and Na<sup>+</sup> dependent (Table 5). Two different cotransport systems for Na<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> have been described, both sensitive to stilbenes and both involved in regulation of p<sub>H<sub>i</sub></sub> after an acid load. An electrogenic Na<sup>+</sup>-2 (or 3) HCO<sub>3</sub><sup>-</sup> cotransport has been found in amphibian (7) and mammalian (18) kidney cells and in the corneal endothelium (19, 33). In barnacle muscle fibers (10), squid axon (5), and snail neuron (31) an electroneutral (Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup>)-(Cl<sup>-</sup>-H<sup>+</sup>) transport was involved in p<sub>H<sub>i</sub></sub> regulation. This system may be identical to the Na<sup>+</sup>-dependent Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchanger found in fibroblasts (23) and epidermoid cells (29) or the NaCO<sub>3</sub>-Cl<sup>-</sup> exchange present in blood cells (4). To differentiate between Cl<sup>-</sup>-dependent and Cl<sup>-</sup>-independent Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> cotransport in PE cells we investigated the properties of p<sub>H<sub>i</sub></sub> regulation in Cl<sup>-</sup>-depleted PE cells. For these experiments cells were kept either for 50 min (during the dye incubation) in HCO<sub>3</sub><sup>-</sup> and Cl<sup>-</sup>-free solutions (Fig. 1E) or for 15 min in HCO<sub>3</sub><sup>-</sup>-containing, Cl<sup>-</sup>-

FIG. 10. After dye loading cells were superfused for 15 min with Cl<sup>-</sup>-free ( $\phi$ Cl<sup>-</sup>) (replaced by cyclamate) HCO<sub>3</sub><sup>-</sup>-containing solution. Subsequently, effect of 1 mM amiloride on recovery of p<sub>H<sub>i</sub></sub> after intracellular acid loading induced by NH<sub>4</sub><sup>+</sup> prepulse technique was tested (6 experiments with similar results).

free media (Fig. 10). Although we did not measure intracellular Cl<sup>-</sup> activities in PE, we can assume from <sup>36</sup>Cl<sup>-</sup> efflux experiments in PE (15) that both procedures reduce intracellular Cl<sup>-</sup> activity by at least 80%. In a previous study in corneal endothelium (19) similar Cl<sup>-</sup> depletion did not inhibit Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> symport. However,

<sup>2</sup>  $K_{m \text{ app}} = K_m \cdot [I] \cdot K_i^{-1} + K_m$ .

in Cl<sup>-</sup>-depleted PE cells the Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> symport was not operating any more (Figs. 1E and 10), suggesting that the Cl<sup>-</sup> depletion was sufficient to inhibit Na<sup>+</sup>-dependent HCO<sub>3</sub><sup>-</sup> influx in PE. Another difference from the Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> symport in the corneal endothelium was found in measurements of membrane potentials in PE. While the symport in the corneal endothelium was clearly electrogenic (33), in PE we could not detect the typical electrical membrane responses of electrogenic Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> symport (Helbig, unpublished observations). Thus there are marked differences between the electrogenic, Cl<sup>-</sup>-independent Na<sup>+</sup>-2 (or 3) HCO<sub>3</sub><sup>-</sup> symport in corneal endothelium and the Cl<sup>-</sup>-dependent Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> symport in the ciliary epithelium.

If the Cl<sup>-</sup>-dependent cotransport for Na<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> is passive, it should be possible to reverse the direction of transport, as has been shown for similar transporters in snail neurone (13) and barnacle muscle (30). Lowering extracellular Na<sup>+</sup> concentration in PE should cause coupled efflux of Na<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> and should acidify pH<sub>i</sub>. In HCO<sub>3</sub><sup>-</sup>-free media Na<sup>+</sup> replacement did not lead to a significant additional acidification in the presence of amiloride (Fig. 6B). In contrast, in HCO<sub>3</sub><sup>-</sup> Ringer solution we found partly amiloride-insensitive and DIDS-sensitive acidification induced by Na<sup>+</sup> replacement (Fig. 6A, Table 3). We conclude that DIDS-sensitive Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> transport in PE can be reversed.

Thus PE cells possess two transport systems for HCO<sub>3</sub><sup>-</sup>: a Na<sup>+</sup>-independent Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchanger and a Cl<sup>-</sup>-dependent Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> transporter. The latter has been shown in squid axon to conform to the kinetics of a NaCO<sub>3</sub>-Cl<sup>-</sup> exchanger (5) but in barnacle muscle this ion-pair model was excluded (10). NaCO<sub>3</sub>-Cl<sup>-</sup> exchange would require only one binding site on the transport protein on each side of the membrane. Both Cl<sup>-</sup>-NaCO<sub>3</sub> and Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange are sensitive to stilbene derivatives and could be mediated by the same transport protein binding either HCO<sub>3</sub><sup>-</sup> or NaCO<sub>3</sub> (4) but would transport alkali equivalents in opposite directions (25). Na<sup>+</sup>-dependent Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange has been shown to be activated by intracellular acidification (11), whereas Na<sup>+</sup>-independent Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange was activated by increasing pH<sub>i</sub> (25, 26). The activation of Na<sup>+</sup>-dependent and Na<sup>+</sup>-independent Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange cannot be solely explained by pH<sub>i</sub>-dependent changes of the intracellular HCO<sub>3</sub><sup>-</sup> and NaCO<sub>3</sub> concentrations. In squid axon ATP-dependent phosphorylation of the transport protein was probably the mechanism of activation of the pH<sub>i</sub>-regulating system by intracellular acidification (9). The stimulation of Na<sup>+</sup>-dependent and Na<sup>+</sup>-independent Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange by opposite pH<sub>i</sub> changes suggests either different transport proteins or two different regulatory states of the same protein. However, it is not clear which ion species were transported in PE. Whether Cl<sup>-</sup>-NaCO<sub>3</sub> exchange, Na<sup>+</sup>-dependent Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange, Cl<sup>-</sup>-dependent Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> cotransport or (Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup>)-(Cl<sup>-</sup>-H<sup>+</sup>) exchange all describe the same transporter has also not been elucidated.

*Regulation of steady-state pH<sub>i</sub>.* Steady-state pH<sub>i</sub> in PE cells is more alkaline than would be predicted if protons are passively distributed across the cell membrane at a membrane potential of -46 mV (17). Furthermore,

changes in pH<sub>o</sub> result in pH<sub>i</sub> changes of less than half the amplitude of changes in pH<sub>o</sub> (Table 1). Thus PE cells possess mechanisms for regulation of steady-state pH<sub>i</sub>. The acidifying action of amiloride during steady state in HCO<sub>3</sub><sup>-</sup>-free solution (Fig. 6B) suggests that Na<sup>+</sup>-H<sup>+</sup> exchange in HCO<sub>3</sub><sup>-</sup>-free medium may be an important (if not the only) regulatory mechanism for steady-state pH<sub>i</sub> in HCO<sub>3</sub><sup>-</sup>-free solution. The Na<sup>+</sup> gradient could extrude protons to even more alkaline pH<sub>i</sub> values than 6.98. Thus there should be a regulatory site that "switches Na<sup>+</sup>-H<sup>+</sup> exchange on or off" depending on pH<sub>i</sub>. Such a regulatory site for internal protons has been described (2). When extracellular media were changed from HCO<sub>3</sub><sup>-</sup>-free to HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub> containing solutions, pH<sub>i</sub> approached a new steady-state value that was about 0.15 pH units more alkaline (Fig. 1A). Similar differences of steady-state pH<sub>i</sub> in HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub>-free and -containing media have been described by others (1). In HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub>-containing media amiloride had no effect on steady-state pH<sub>i</sub> (Fig. 6A), suggesting that Na<sup>+</sup>-H<sup>+</sup> exchange was not necessary for regulation of steady-state pH<sub>i</sub> in HCO<sub>3</sub><sup>-</sup>-containing solution. We have shown that the delayed alkalization on HCO<sub>3</sub><sup>-</sup>-CO<sub>2</sub> addition was not inhibited by amiloride, but was nearly abolished by DIDS in Cl<sup>-</sup>-depleted cells and in Na<sup>+</sup>-free media (Fig. 1). These are the same characteristics as described above for the HCO<sub>3</sub><sup>-</sup> transporter involved in pH<sub>i</sub> recovery after NH<sub>4</sub><sup>+</sup> prepulse. HCO<sub>3</sub><sup>-</sup> accumulation by Cl<sup>-</sup>-dependent Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> cotransport seems to be the major process responsible for maintenance of steady-state pH<sub>i</sub> in HCO<sub>3</sub><sup>-</sup> Ringer solution. The set point for the HCO<sub>3</sub><sup>-</sup> transporter and for the Na<sup>+</sup>-H<sup>+</sup> exchange, both denoted as "smart" transporters because of their pH<sub>i</sub> sensitivity (6), in PE cells is different. Na<sup>+</sup>-H<sup>+</sup> exchange will be only activated when pH<sub>i</sub> falls to ~0.15 pH units below steady-state pH<sub>i</sub> in HCO<sub>3</sub><sup>-</sup> Ringer solution, which is maintained by the Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> transport.

The PE cells used in the present study were obtained after transformation with SV-40. This may have changed their physiological properties. However, our results from isotope-uptake experiments provided evidence for Na<sup>+</sup>-H<sup>+</sup> exchange (14), Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange (15) and Cl<sup>-</sup>-dependent Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> symport (unpublished observations) in primary cultured PE. Thus the transporters described in the present study in virus-transformed PE are also present in nontransformed PE.

In conclusion, PE cells possess two HCO<sub>3</sub><sup>-</sup> transport systems in addition to Na<sup>+</sup>-H<sup>+</sup> exchange: 1) Na<sup>+</sup>-independent Cl<sup>-</sup>-HCO<sub>3</sub><sup>-</sup> exchange involved in pH<sub>i</sub> recovery after alkali load, and 2) Cl<sup>-</sup>-dependent Na<sup>+</sup>-HCO<sub>3</sub><sup>-</sup> cotransport responsible for maintenance of steady-state pH<sub>i</sub> and regulation of pH<sub>i</sub> after an acid load. In addition, these transporters may be involved in transepithelial transport across the ciliary epithelium. Coupled transport of Na<sup>+</sup> and HCO<sub>3</sub><sup>-</sup> could be an important mechanism for aqueous humor formation.
